M. Burekhardt is of opinion, that Le Monnier had observed this planet as a fixed star, since a small star, situated in the same place, and observed by that astronomer, has since disappeared.

The following are the elements of the orbit of Vesta, computed by Mr. Groombridge, from his own observations.

Revolution	3 ^y 182
According to others (see <i>Planetary NUMBERS</i>) in	1335 ^d 0 ^h 23'
Place of aphelion	6° 3' 0' 0"
Place of ascending node	3 14 38 0
Inclination of orbit	7 8 20
Mean distance	2.163
Excentricity in parts of the Earth's radius	0.0953

The following elements are given by Burekhardt, in the *Connoissance de Temps* for 1809, from the most recent observations on the continent.

Mean distance	-	-	2.373000
Excentricity	-	-	0.093221

We shall subjoin to the account above given of the four new planets, called by Dr. Herschel *asteroids* (which see), some observations concerning their origin. From a variety of considerations it has been concluded, agreeably to the opinion suggested by Dr. Olbers, that these four planets are the fragments of a large celestial body, which once existed between Mars and Jupiter. On the supposition that they are independent planets, their diminutive size, the great excentricity and inclination of their orbits, and their numerous intersections, when projected on the plane of the ecliptic, are phenomena absolutely inexplicable on every principle of science, and completely subversive of that harmony and order, which, before the discovery of these bodies, pervaded the planetary system. But if we admit the hypothesis, that these planets are the remains of a larger body, which circulated round the sun, nearly in the orbit of the greatest fragment, the system resumes its order, and we discover a regular progression in the distances of the planets, and a general harmony in the form and position of their orbits. Thus does the ingenious Dr. Brewster introduce his general reasoning on this subject. He then proceeds to observe, that the elements of the new planets furnish us with several direct arguments, drawn from the excentricity and inclination of their orbits, and from the position of their perihelia and nodes, and all concurring to shew, that the four new planets have diverged from one point of space, and have, therefore, been originally combined in a larger body. When the original planet burst in pieces, by some internal force capable of overcoming the mutual attraction of the fragments, the larger fragment must obviously receive the least impetus from the explosive force, and circulate in an orbit deviating less than any other of the fragments from the original path of the large planet; while the lesser fragments, being thrown off with greater velocity, would revolve in orbits more excentric, and more inclined to the ecliptic. Applying this remark to the case before us, the excentricity of Ceres and Vesta is nearly one-twelfth of their mean distance, that of Ceres being rather the greatest; and the excentricity of Pallas and Juno is one-fourth of their mean distance, that of Pallas being a little greater than that of Juno. From the theory it might be expected, that Pallas and Juno would be considerably smaller than Ceres and Vesta, and that Ceres should be the larger fragment, and have an orbit more analogous in excentricity and inclination than any of the smaller fragments to the other planets of the system. As far as the diameters of the new planets have been measured, the theory is very strikingly confirmed by observation. According to Dr. Herschel, the diameter of Ceres is 163 miles, while that of Pallas is only 80. The observations of Schroeter make Juno considerably less than Ceres; and though the diameter of Vesta has not been accurately ascertained, yet the intensity of its light, and the circumstance of its being distinctly visible to the naked eye, are strong proofs that it exceeds in magnitude both Pallas and Juno. The striking resemblance between the two lesser fragments, Pallas and Juno, in their magnitudes, and in the extreme excentricity of their orbits, would lead us to anticipate similar resemblances in the position of their nodes, in the place of their perihelia, and in the inclination of their orbits; while the elements of Ceres and Vesta should exhibit similar coincidences. Now, the inclination of Ceres is 10°, and that of Vesta 7°; while the inclination of Juno is 21°,

and that of Pallas 34°; the two greater fragments having nearly the same inclination, and keeping near the ecliptic, while the lesser fragments diverge from the original path, and rise to a great height above the ecliptic, and far above the orbits of all the other planets in the system. If it shall be found, from observation, that Vesta is one of the smaller fragments, we may then account for its position with regard to Ceres, and for the small inclination and excentricity of its orbit, by supposing the planets Ceres, Pallas, and Juno, to have diverged in the same plane, and nearly at right angles to the ecliptic, while Vesta diverged from the direction of the original planet, in a plane parallel with the ecliptic. This opinion is strongly confirmed by the fact, that the orbit of Vesta is nearer to the sun than either of the orbits of the other three fragments. The same coincidence is apparent in the position of the nodes. The orbits of Pallas and Juno cut the ecliptic in the same point, and the nodes of Ceres and Vesta are not far distant. If all the fragments of the original planet had, after the explosion, been attracted to the larger fragment, it is obvious that they would all move in the same orbit, and consequently have the same perihelion. If the fragments received a slight degree of divergency from the explosive force, and moved in separate orbits, the points of their perihelion would not coincide, and their separation would increase with the divergency of the fragments. But, since all the fragments partook of the motion of the primitive planet, the angle of divergency could never be very great; and, therefore, we should expect that all the perihelia of the new planets would be in the same quarter of the heavens. This theoretical deduction is most wonderfully confirmed by observation. These singular resemblances, as our author closes his reasoning on this subject, in the motions of the greater fragments, and in those of the lesser fragments, and the striking coincidences between theory and observation in the excentricity of their orbits, in their inclination to the ecliptic, in the position of their nodes, and in the places of their perihelia, are phenomena which could not possibly result from chance, and which concur to prove, with an evidence amounting almost to demonstration, that the four new planets have diverged from one common node, and have therefore composed a single planet. Our author proceeds to account for the origin of meteoric stones, which he considers as phenomena that might accompany this great convulsion. Ferguson's *Astronomy*, by Dr. Brewster, vol. ii. See *BALLS of Fire*, *FALLING Stones*, and *GEORGIUM SIDUS*.

Saturn is represented by the character ♄. This planet, on account of its great distance, appears to the eye with a feeble light. It performs its revolution round the sun in about thirty years. See SATURN.

Jupiter, marked ♃, is a bright resplendent star, finishing its course round the sun in about twelve years. See JUPITER.

Vesta has no character assigned it. See VESTA.

Juno is represented by the character ♃. See JUNO.

Pallas is exhibited under the character ♃. See PALLAS.

Ceres is marked by ♃. See CERES.

Mars, characterized ♃, is a ruddy fiery-coloured planet, finishing its course in about two years. See MARS.

The Earth, marked ⊕, performs its revolution in one year. See EARTH.

Venus, ♀, is the brightest of all the planets, constantly attending the sun, and never distant from him above 48 degrees. It finishes its course in about seven months.

When it goes before the sun, it is called *Phosphorus* and *Lucifer*; and when it follows him, *Hesperus*.

Mercury, ☿, a little bright planet, the sun's constant companion, from whose side it never departs above 28 degrees, and by that means is usually hid in his splendour.

PLANET.

It performs its course in about three months. See **MERCURY**.

From these definitions, a person may easily distinguish all the planets. For, if after sun-set he sees a planet nearer the east than the west, he may conclude it is neither Mercury nor Venus; and may determine whether it is Saturn, Jupiter, or Mars, by the colour and light: by which also he may distinguish between Mercury and Venus.

PLANETS, Nature of the. From the several phases and appearances of the planets, they are found to be all like the moon, which we have shewn to be like our earth; whence it follows, that the planets are also dark, opaque, spherical, &c. bodies, like our earth.

This may be shewn almost to a demonstration.

The phases of Mercury are easily distinguished to be like those of Venus; but no spots have yet been discovered, by which we can ascertain whether it has any rotation. Although Dr. Herschel affirms, in consequence of his observations of this planet, that it appears equally luminous in every part of its body, and that its disc is always well defined, without any spot or ragged edge, Mr. Schroeter thinks that he has discovered not only spots, but mountains in Mercury. He measured two of these mountains, the highest of which was 8900 toises, or $10\frac{3}{4}$ miles, or more than double the height of Chimboraco in the Andes; and the other was little more than 1000 toises high. From the variations in the daily appearance of Mercury's horns, this astronomer infers that the period of its daily rotation was $24^h 5' 28''$. These observations remain to be confirmed.

Venus, observed with a telescope, is rarely found full, but with variable phases like those of the moon; her illuminated part still turned towards the sun, *viz.* towards the east when she is the morning-star, and towards the west when the evening-star.

The phases of Venus were first discovered in 1611 by Galileo, who sent an account of the discovery to William de Medici, in order to have it communicated to Kepler. He transmitted it in this cypher, "Hæc immatura a me frustra leguntur, o.7;" which, duly arranged, is "Cynthiæ figuræ æmulatur mater amorum," *i. e.* Venus emulates the phases of the moon. Afterwards he wrote a letter to him, giving an account of the discovery, and explaining the cypher. In 1666, M. Cassini, at a time when Venus was dichotomized, discovered a bright spot upon it at the straight edge, like some of the bright spots upon the moon's surface; and by observing its motion, which was upon the edge, he found the sidereal time of rotation to be $23^h 16'$. In the year 1726, Bianchini made some observations upon the spots of Venus, and asserted that the time of rotation was $24\frac{1}{2}$ days; that the north pole answered to the 20th degree of Aquarius, and was elevated from 15° to 20° above its orbit; and that the axis continued parallel to itself. M. Cassini, the son, vindicated his father's observations, and took occasion, from the interruption of Bianchini's observations, to shew that she might easily mistake different spots for the same; and he concludes, that if we suppose the time of rotation to be $23^h 20'$, it agrees equally with their observations; but if we take it to be $24\frac{1}{2}$ days, it will not at all agree with his father's observations. M. Schroeter has endeavoured to shew that Venus has an atmosphere, from observing that the illuminated limb, when horned, exceeds a semicircle; and this he supposes to arise from the refraction of the sun's rays through the atmosphere of Venus at the cusps, by which they appear prolonged. The cusps appeared sometimes to run $15^\circ 19'$ into the dark hemisphere; from which he computes, that the height of the atmosphere, for refracting such a quantity of light, must be 15,156 Paris feet; but this must depend on the nature and density of the atmosphere, of

which we are ignorant. (See Phil. Transf. for 1792.) He makes the time of rotation to be $23^h 21'$; and concludes, from his observations, that there are considerable mountains upon this planet.

He found that, like those of Mercury and of the moon, those of the southern hemisphere were the highest; their perpendicular heights being nearly as the diameters of their respective planets. M. Schroeter measured the height of four mountains in Venus, and obtained the following results; *viz.*

	Toises.	Miles.
1st Highest	- 18900	22.05
2d Highest	- 15750	18.97
3d Highest	- 9500	11.44
4th Highest	- 9000	10.84

This planet has generally been considered as about 220 miles less in diameter than the earth; but from the measurements of Dr. Herschel, whose accuracy cannot be questioned, it is inferred that when reduced to the mean distance of the earth, her apparent mean diameter is $18''.79$, that of the earth being $17''.2$, that is, 8648 English miles, the diameter of the earth being 7912. Phil. Transf. for 1795. See **VENUS**.

M. de la Hire, in 1700, with a telescope of sixteen feet, discovered mountains in Venus, larger than those of the moon.

Dr. Herschel agrees with M. Schroeter in supposing that Venus has a considerable atmosphere; but he has not made any observations by which he can determine either the time of rotation, or the position of the axis. See Phil. Transf. for 1793.

Gassendus first, and after him others, have observed Mercury on the face of the sun, across which he appeared to pass like a black round spot. Horrox, in 1639, also observed Venus in the sun, where she made the same appearance. Two transits have been since observed, and those of Mercury are more frequent. See **PARALLAX** and **TRANSIT**.

Galileo discovered the phases of Mars; after which some Italians, in 1636, had an imperfect view of a spot. But in 1666 Dr. Hooke and M. Cassini discovered some well defined spots, observed likewise by Campani; and Cassini determined the time of the rotation to be $24^h 40'$. Soon after, M. Maraldi observed some spots, and determined the time of rotation to be $24^h 39'$. He also observed a very bright part near the southern pole, apparently like a polar zone; this, he says, has been observed for 60 years; it is not of equal brightness; more than half of it being brighter than the rest; and that part which is least bright is subject to great changes, and sometimes disappears. Something of the same kind has been observed about the north pole. The rotation is according to the order of the signs. Dr. Herschel makes the time of a sidereal revolution to be $24^h 39' 21''.67$, without the probability of a greater error than $2''.34$. He proposes to find the time of a sidereal rotation, in order to discover, by future observations, whether there is any alteration in the time of the revolution of the earth, or of the planets, about their axes; for a change of either would be thus discovered. He chose Mars, because its spots are permanent. (See Phil. Transf. for 1781.) From farther observations upon Mars, which he published in Phil. Transf. for 1784, he makes its axis to be inclined to the ecliptic $59^\circ 42'$, and $61^\circ 18'$ to its orbit; and the north pole to be directed to $17^\circ 47'$ of Pisces upon the ecliptic, and $19^\circ 28'$ on its orbit. He makes the ratio of the diameters of Mars to be as 16 to 15. Dr. Maskelyne has carefully observed Mars at the time of opposition, but could not perceive any difference in its diameters. Dr. Herschel observes, that Mars has a considerable atmosphere, the density of which occasions the redness of its light. La Place has computed the density of this planet to be $\frac{3}{4}$ ths that of the earth. See **MARS**.

Jupiter is observed to have belts, and also spots, by which the time of its rotation can be more accurately ascertained:

PLANET.

tained. These belts were first observed by two Jesuits, Zuppi and Bartoli. They were afterwards examined in 1633 by Fontana, Rheita, Riccioli, Grimaldi and Campani. M. Cassini found the time of rotation to be $9^h 56'$, from a remarkable spot which he observed in 1665. In October, 1691, he observed two bright spots, almost as broad as the belts; and at the end of the month he saw two more, and found them to revolve in $9^h 51'$; he also observed some other spots near Jupiter's equator, which revolved in $9^h 50'$; and, in general, he found that the nearer the spots were to the equator, the quicker they revolved. It is, therefore, probable, that the spots are not upon Jupiter's surface, but in its atmosphere; and for this reason also, that several spots, which appeared round at first, grew oblong by degrees, in a direction parallel to the belts, and divided themselves into two or three spots. M. Maraldi, from a great many observations of the spot observed by Cassini in 1665, found the time of rotation to be $9^h 56'$: and concluded that the spots had a dependence upon the contiguous belt, as the spot had never appeared without the belt, though the belt had been seen without the spot. It continued to appear and disappear, until the year 1694, and was not seen any more until the year 1708; hence he concluded, that the spot was some effusion from the belt upon a fixed place of Jupiter's body: for it always appeared in the same place. Dr. Herschel found the time of rotation of different spots to vary; and that the time of rotation of the same spots diminished, for the spot observed in 1788 revolved as follows. From February the 25th to March the 2d, in $9^h 55' 20''$; from March the 2d to the 14th, in $9^h 54' 58''$; from April the 7th to the 12th, in $9^h 51' 35''$. Also, from a spot observed in 1779, its rotation was, from April the 14th to the 19th, in $9^h 51' 45''$; from April the 19th to the 23d., in $9^h 50' 48''$. This, he observes, is agreeable to the theory of equinoctial winds, as it may be some time before the spot can acquire the velocity of the wind; and if Jupiter's spots should be observed in different parts of its revolution to be accelerated and retarded, it would amount almost to a demonstration of its moons, and their periodical changes. M. Schroeter makes the time of rotation $9^h 55' 36''.6$; and he observed the same variations with those of Dr. Herschel. The rotation is according to the order of the signs. This planet is observed to be flat at its poles. Dr. Pound measured the polar and equatorial diameters, and found them to be as 12 to 13. Mr. Short made them as 13 to 14. Dr. Bradley made them as 12.5 to 13.5. Sir Isaac Newton makes the ratio $9\frac{1}{2}$ to $10\frac{1}{2}$ by theory. The belts of Jupiter are generally parallel to its equator, which is very nearly parallel to the ecliptic: they are subject to great variations, in respect both to their number and figure: sometimes eight have been seen at once, and at other times only one: sometimes they continue for three months without any variation, and sometimes a new belt has been formed in an hour or two. From their being subject to such changes, it is very probable that they do not adhere to the body of Jupiter, but exist in its atmosphere. Others, however, imagine that they are of a more permanent nature, and that they indicate great physical revolutions, which are perpetually agitating and changing the surface of the planet. It is suggested by Dr. Brewster (Ferguson's Astronomy, vol. ii.) that the spot first observed by Cassini, already mentioned, could not possibly be occasioned by any atmospheric variations; and that its disappearance for five years, between 1708 and 1713, affords a presumptive, though not a decisive argument, that it arose from some changes in the body of the planet. He inclines to think, that from the frequent appearance of this spot, it is permanent upon the body of Jupiter, and that its disappearance is owing to the interposition of clouds in the atmo-

sphere of the planet. He farther intimates, that the clouds of Jupiter, partaking of the great velocity of its diurnal motion, are formed into strata parallel with the equator; that the body of Jupiter reflects less light than the clouds; and that the belts are nothing more than the body of the planet seen through the parallel interstices which lie between the different strata of clouds. The permanent spot of Cassini will, of course, only be seen when it is immediately below one of these interstices, and will therefore always appear as if it accompanied one of the belts. See JUPITER and SATELLITES.

Saturn was suspected by Cassini and Fatio, in 1683, to have a revolution about its axis, for they one day saw a bright streak, which disappeared the next, when another came into view near the edge of its disc: these streaks are called "belts." In 1719, when the ring disappeared, Cassini saw its shadow upon the body of the planet, and a belt on each side parallel to the shadow. When the ring was visible, he perceived the curvature of the belts was such as agreed with the elevation of the eye above the plane of the ring. He considered them as similar to our clouds floating in the air; and having a curvature similar to the exterior circumference of the ring, he concluded that they ought to be nearly at the same distance from the planet, and that consequently the atmosphere of Saturn extended to the ring. Huygens observed five belts, which were nearly parallel to the equator. Dr. Herschel found that the arrangement of the belts always followed the direction of the ring: thus, as the ring opened, the belts began to shew an incurvature answering to it. And during his observations on June the 19th, 20th, and 21st, in the year 1780, he saw the same spot in three different situations. He conjectured, therefore, that Saturn revolved about an axis perpendicular to the plane of its ring. Another argument in support of this is, that the planet is an oblate spheroid, having the diameter in the direction of the ring to the diameter perpendicular to it, as about 11 to 10, according to Dr. Herschel; the measures were taken with a wire micrometer, prefixed to his 20-foot reflector. The truth of his conjecture he has now verified, having determined that Saturn revolves about its axis in $10^h 16' 0''.44$. (See Phil. Transf. for 1794.) La Place had formerly found that the interior ring ought to perform its revolution in ten hours. (Mem. Acad. 1787.) The rotation is according to the order of the signs.

In 1789 Dr. Herschel measured the diameter of this planet, and found that the equatorial diameter was $22''.8$, and the polar diameter $20''.6$; which gives the proportion nearly of 10 to 11. But from more recent observations, he inferred that the polar is to the equatorial diameter as 32 to 35, or as 11 to 12 nearly. Until the year 1805 Dr. Herschel had always regarded Saturn as an accurate spheroid, but in April of that year he was struck with a very singular appearance exhibited by the planet. The flattening at the poles did not seem to begin till a very high latitude; so that the real figure of the planet resembled a square, or rather a parallelogram, with the four corners rounded off deeply, but not so much as to bring it to a spheroid. (See Phil. Transf. for 1805.) The following are the proportional dimensions of Saturn's disc.

Diameter of the greatest curvature	-	36
Equatorial diameter	-	35
Polar diameter.	-	32
Latitude of the longest diameter	-	$43^{\circ} 20'$

See RING and SATURN.

The Georgian planet is at so great a distance, that astronomers with their best telescopes, have not been able to discover whether or not it has any revolution about its axis. Since the Sun (see SUN), Moon (see MOON), Saturn, Jupiter, Mars, the Earth, and Venus, are found to revolve

PLANET.

on their axes, *i. e.* to have a diurnal rotation, we may argue from analogy that Mercury and the Georgian have the same; although the proximity of the former to the sun, and the great distance of the latter prevent any spots from being observed in them, by which that rotation might be demonstrated.

Moreover, in the year 1609, were first observed the little stars or moons, moving about Jupiter, by Sim. Marius; and in 1610 the same were observed by Galileo: these are now frequently observed to disappear in a clear sky, when Jupiter happens to be diametrically interposed between them and the sun. Whence it appears that they are void of light, at such time when the sun's rays, intercepted by Jupiter, cannot be propagated to them in right lines; and hence also that, like the moon, they are opaque bodies illuminated by the sun; and hence again, since Jupiter does not illuminate his satellites when placed behind him, he himself, in that part turned from the sun, may be argued to be void of light.

When Jupiter's moons are diametrically interposed between Jupiter and the sun, there is seen a round spot on Jupiter's disk, which is sometimes larger than the satellite itself. Whence it appears, that the satellites are opaque bodies, illuminated by the sun; that they project a shadow from the sun; and that the round spots, seen in Jupiter, are the shadows of the satellites.

Whence, also, the intersection of that shadow being found to be a circle, the shadow must be conical; and therefore the figure of the satellites, at least as to sense, is spherical.

The earth being between Jupiter and the sun; if, at the same time, any one of the satellites happen to be between Jupiter and the sun, it is lost in Jupiter's light; though sometimes appearing like a black spot. This phenomenon has been frequently observed by Cassini and Maraldi who have likewise noted very considerable alterations in the apparent magnitudes of the satellites; for which no reason could be given from the distance of Jupiter, the sun, or the earth: *e. gr.* that the fourth, which is usually seen the smallest, is sometimes the largest; and the third, which is usually the largest, appears sometimes the smallest. Hence, as the satellites are illuminated by the sun, even when immersed in Jupiter's light, yet do appear obscure, there must be some alteration in their atmospheres, to prevent the sun's rays being equally reflected from every part of their surface; which must likewise be the cause why their shadow is sometimes larger than themselves. See **SATELLITES**.

Now, to sum up the evidence resulting from the preceding detail of observations: 1. Since in Venus, Mercury, and Mars, only that part of the disc illuminated by the sun, is found to shine; and, again, Venus, and Mercury, when between the earth and the sun, appear like dark spots, or maculæ, on the sun's disc, it is evident, that Mars, Jupiter, and Mercury, are opaque bodies, illuminated with the borrowed light of the sun. And the same appears of Jupiter, from its being void of light in that part to which the shadow of the satellites reaches, as well as in that part turned from the sun; and that his satellites are opaque, and reflect the sun's light, is also abundantly shewn. Wherefore, since Saturn, with his ring and satellites, do only yield a faint light, fainter considerably than that of the fixed stars, though these be vastly more remote, and than that of the rest of the planets, it is past doubt, that he too, with his attendants, are opaque bodies.

Since the sun's light is not transmitted through Mercury and Venus, when placed against him, it is plain they are dense opaque bodies; which is likewise evident in Jupiter, from his hiding the satellites in his shadow; and therefore, by analogy, the same may be concluded of Saturn.

From the variable spots in Venus, Mars, and Jupiter, some have concluded that those planets have a changeable

atmosphere; which changeable atmosphere may, by a like argument, be inferred of the satellites of Jupiter; and therefore, by similitude, the same may be concluded of the other planets.

In like manner, from the mountains observed in Venus, the same may be supposed in the other planets.

Since then Saturn, Jupiter, the satellites of both, Mars, Venus, and Mercury, are opaque bodies, shining with the sun's borrowed light, and are furnished with mountains, and encompassed, as some have supposed, with a changeable atmosphere, they have, of consequence, waters, seas, &c. as well as dry land, and they are bodies, therefore, like the earth. Q. E. D.

And hence nothing hinders but that the planets may also be concluded to be inhabited. Huygens, in his Cosmotheoros, argues very plausibly for the existence of planetary inhabitants, from the similitude of the planets with our earth: those, like this, being opaque, dense, uneven, round, heavy, illuminated, and warmed by the sun, having night and day, summer and winter, &c.

Wolffius deduces something relating to this purpose from arguments of another kind. Thus, *e. gr.* it is scarcely to be doubted, that the inhabitants of Jupiter are much larger than those of the earth, and, in effect, of the giant kind. For it is shewn in optics, that the pupil of the eye dilates in a strong light, and contracts in a weak one: wherefore, since in Jupiter the sun's meridian light is much feebler than on the earth, on account of Jupiter's greater distance from the sun, the pupil will need to be much more dilatate in the inhabitants of Jupiter than in those of the earth. But the pupil is observed to have a constant proportion to the ball of the eye, and the eye to the rest of the body; so that in animals, the larger the pupil the larger the eye, and the larger the body.

To ascertain the size of these jovial inhabitants, it may be observed, that the distance of Jupiter from the sun is to the earth's distance from the same, as 28 to 5; the intensity of the sun's light in Jupiter is to its intensity on the earth, in a duplicate ratio of 5 to 28; but it is found by experience, that the pupil dilates in a ratio greater than that in which the intensity of light decreases; otherwise a body at a great distance might be seen as clearly as a nearer; the diameter, therefore, of the pupil in its greatest dilatation, in the earth, is to its diameter in the like state in Jupiter, in a ratio greater than that of the duplicate of 5 to 28. If then we put it as 10 to 28, or as 5 to 14: since the ordinary stature of the inhabitants of the earth is computed at 5 English feet 4 inches and $\frac{3}{4}$ ths, (which Wolffius tells us was his own height,) the ordinary stature of Jupiter's inhabitants will be found about 14 feet 3ds, which is very nearly the size of the giant Og, mentioned by Moses, whose iron bed was nine cubits long, and its breadth four. But arguments of this kind being more whimsical than solid, are needless, in order to justify the similarity of the other planets to our earth, and a conjecture, that they are destined by the Creator for the same purpose.

For an account of the relative and real magnitudes, the proportional and actual distances, annual and diurnal revolutions, &c. of the planets, both primary and secondary, see **SUN**, **Solar SYSTEM**, **MOON**, **SATELLITES**, each planet under its proper name, and the references in the sequel of this article.

The quantities of matter in the Sun, Jupiter, Saturn, and the Earth, as determined by the Newtonian theory of gravity, are to each other as the numbers 1, 1087, 1087, 1087, 1087; and their densities as the numbers 100, $94\frac{1}{2}$, 67, and 400; and their attractive powers at their surfaces as the numbers 10,000, 943, 529, 435, respectively. For a more correct statement, see **DENSITY**.

For

PLANET.

For the places and motion of the aphelia of the planets, and the method of determining them, see APHELION.

For the diameters of the sun and planets, as seen from the earth, and the diameters of the planets, as seen from the sun, see DIAMETER.

For the relative mean distances of the planets from the sun, see DISTANCE.

The greatest equations of the planets are as follow: Mercury, $23^{\circ} 40' 0''$; Venus, $0^{\circ} 47' 20''$; the Earth, $1^{\circ} 55' 36''.5$; Mars, $10^{\circ} 40' 40''$; Jupiter, $5^{\circ} 30' 38''.3$; Saturn, $6^{\circ} 26' 42''$; the Georgian, $5^{\circ} 27' 16''$. See EQUATION.

The following table exhibits the relation of the densities, diameters, quantities of matter, and gravity on the surfaces of the sun and planets, respectively.

Planets.	Densities.	Diameters.	Quantities of Matter.	Gravity on Surfaces.
Sun	0.25226	109.8	333928	27.7
Mercury	2.5833	0.4	0.16536	1.0333

The intensities of light and heat which the planets receive from the sun, vary inversely as the squares of their distances from the sun: and the apparent diameter of a body is inversely as its distance; and therefore assuming the mean diameter of the sun = 32', we shall have his apparent diameter at the several planets as follows.

The following table exhibits the relative intensities of light and heat at the different planets, and the apparent diameter of the Sun seen from them.

Planets.	Intensities of Light and Heat.	Apparent Diameter of the Sun.
Mercury	6.25	80'
Venus	2.04	45.7
Earth	1	32
Mars	0.44375	21.33
Jupiter	0.036875	6.15
Saturn	0.01106	3.37
Georgian	0.00276	1.64

The orbits of the planets are all ellipses; one of whose foci is in the sun. This Kepler first found from Tycho's observations; before him, all astronomers took the planetary orbits for excentric circles. The manner in which he proceeded was as follows.

Let S (*Plate XIX. Astronomy, fig. 3.*) be the sun, M Mars, D, E, two places of the earth when Mars is in the same point M of its orbit. When the earth was at D, he observed the difference between the longitudes of the sun and Mars, or the angle M D S; in like manner, he observed the angle M E S. Now the places D, E, of the earth in its orbit being known, the distances D S, E S, and the angle D S E, will be known; hence, in the triangle D S E, we know D S, S E, and the angle D S E, to find D E, and the angles S D E, S E D; hence we know the angles M D E, M E D, and D E, to find M D; and lastly, in the triangle M D S, we know M D, D S, and the angle M D S, to find M S, the distance of Mars from the sun. He also found the angle M S D, the difference of the heliocentric longitudes of Mars and the earth. By this method, Kepler, from observations made on Mars when in aphelion and perihelion (for he had determined the position of the line of the apides, by a method independent of the form of the orbit), determined the former distance from the sun to be 166780, and the latter 138500, the mean distance of the earth from the sun being 100000; hence, the mean distance of Mars was 152640, and the excentricity of its orbit 14140. He then determined, in like manner, three other distances, and found them to be 147750, 163100, 166255. He next calculated the same three distances, upon supposition that the orbit was a circle, and found them to be 148539, 163883, 166605; the errors therefore of the circular hypothesis were 789, 783, 350. But he had too good an opinion of Tycho's observations, (upon which he founded all these calculations,) to suppose that these differences might arise from their inaccuracy; and as the distance between the aphelion and perihelion was too great, upon supposition that the orbit was a circle, he knew that the form of the orbit must be an oval: "Itaque planè hoc est: Orbita planetæ non est circulus, sed ingrediens ad latera utraque paulatim, iterumque ad circuli amplitudinem in perigæo exiens, ejusmodi figuram itineris ovalem appellitant," p. 213. And as, of all ovals, the ellipse appeared to be the most simple, he first supposed the orbit to be an ellipse, and placed the sun in one of the foci; and upon calculating the above observed distances, he found they agreed together. He did the same for other points of the orbit, and found that they all agreed: and thus he pronounced the orbit of Mars to be an ellipse, having the sun in one of its foci. Having determined this for the orbit of Mars, he conjectured the same to be true for all the other planets, and upon trial he found it to be so. Hence, he concluded, "that the six primary planets revolve about the sun in ellipses, having the sun in one of the foci."

The relative mean distances of the planets from the sun are as follow: Mercury, 38710; Venus, 72333; Earth, 100000; Mars, 152369; Jupiter, 520279; Saturn, 954072; Georgian, 1918352.

Having thus discovered the relative mean distances of the planets from the sun, and knowing their periodic times, he next endeavoured to find if there was any relation between them, having had a strong passion for finding analogies in nature. On March 8, 1618, he began to compare the powers of these quantities, and at that time he took the squares of the periodic times, and compared them with the cubes of the mean distances, but, from some error in the calculation, they did not agree. But on May 15, having made the last

PLANET.

calculations again, he discovered his error, and found an exact agreement between them. Thus he discovered that famous law, "That the squares of the periodic times of all the planets are as the cubes of their mean distances from the sun." Sir I. Newton afterwards proved that this is a necessary consequence of the motion of a body in an ellipse, revolving about the focus. Prin. Phil. lib. i. sec. 2. pr. 15.

Kepler also discovered, from observation, that the velocities of the planets, when in their apses, are inversely as their distances from the sun; whence it followed, that they describe in these points equal areas about the sun in equal times. And although he could not prove, from observation, that the same was true in every point of the orbit, yet he had no doubt but that it was so. He therefore applied this principle to find the equation of the orbit, and finding that his calculations agreed with observations, he concluded that it was true in general, "That the planets describe about the sun equal areas in equal times." This discovery was, perhaps, the foundation of the "Principia," as it might probably suggest to sir I. Newton the idea, that the proposition was true in general, which he afterwards proved it to be. These important discoveries are the foundation of all astronomy. Vince's Elem. of Astronomy.

The planes of the planetary orbits do all intersect in the sun; and the line in which the plane of each orbit cuts that of the earth, is called the *line of the nodes*; and the two points in which the orbits themselves touch that plane, the *nodes*. For the longitude of the nodes of the planets, see NODE.

The motion of the nodes is found by comparing their places at two different times; whence that of Mercury in 100 years is found to be $1^{\circ} 12' 10''$; that of Venus, $0^{\circ} 51' 40''$; that of Mars, $0^{\circ} 46' 40''$; that of Jupiter, $0^{\circ} 59' 30''$; that of Saturn, $0^{\circ} 55' 30''$. This motion is in respect to the equinox. The Georgian planet has not been discovered long enough to admit of determining the motion of its nodes by observation. M. de la Grange has found the annual motion to be $12''.5$ by theory; but if we take the density of Venus according to M. de la Lande, it will be $20'' 40'''$, which he uses in his table.

The distance between the centre of the sun and the centre of each object, is called the *eccentricity of the planet*. For the eccentricities of the planets, see ECCENTRICITY.

The angle at which each plane cuts that of the ecliptic, is called the *inclination of the plane*.

The inclinations of the orbits of the planets are as follow: that of Mercury, $7^{\circ} 0' 0''$; that of Venus, $3^{\circ} 23' 35''$; that of Mars, $1^{\circ} 51' 0''$; that of Jupiter, $1^{\circ} 18' 56''$; that of Saturn, $2^{\circ} 29' 50''$; and that of the Georgian, $46' 20''$. (See NODE.) For the elements of the orbits of Ceres, Pallas, Juno, and Vesta; see the preceding part of this article. See also *Planetary NUMBERS*.

PLANETS, Motion of the. That the planets do all revolve round the sun as their centre, and not round the earth, is evident from a thousand phenomena. 1. The orbit in which Venus, *c. gr.* moves, does certainly encompass the sun; and therefore, in describing that orbit, the planet must turn round the sun.

That her orbit includes the sun, appears hence, that she is sometimes above the sun, sometimes below it, sometimes beyond it, and sometimes on this side; all which are evident from the circumstances of her phases.

That she does not move round the earth, is no less apparent, from her being ever observed in the same quarter with the sun, never receding from him above 48° . She never, therefore, comes to be in opposition to the sun; no, not to be in a quartile aspect, or to have a quarter of the heavens between them; both which, like the earth, she

must frequently have, did she attend and move round the earth.

2. That Mercury revolves round the sun, appears in like manner from his phases, which resemble those of Venus and the moon; and from its neighbourhood to the sun, from whom Mercury never recedes so far as Venus does.

3. That the orbit of Mars includes the sun, is evident from that planet's being found both in conjunction and opposition with the sun; and in both cases shining with a full face. Indeed, from the same circumstances it appears, that the orbit of Mars encompasses the earth; but then it follows, likewise, from Mars's diameter appearing seven times as big when in opposition as when in conjunction, that he is seven times nearer the earth in the former than in the latter position. The earth, therefore, is far from being the centre of Mars's motion; but Mars is ever nearly at the same distance from the sun. Again, Mars viewed from the earth moves very irregularly; is sometimes seen to proceed slower, sometimes faster; sometimes he stands still, and sometimes he goes backward, (the reason of which see under the article *OPTICAL Inequality*); but viewed from the sun, he will ever appear to move with the same constant uniform tenor; whence it is evident he respects the sun, not the earth, as the centre of his motion.

4. The same appearances whence Mars is shewn to revolve round the sun as a centre, are likewise observed in Jupiter and Saturn; whence the same conclusion may be made of them.

Lastly, that the earth revolves round the sun, as a centre, is evident from her place, which we have observed to be between the orbits of Mars and Venus; and from the phenomena of the superior planets viewed from it. If the earth stood still, we should never see those planets either stationary or retrograde; the earth therefore moves, but it is still found between the orbits of Mars and Venus, which encompasses the sun; therefore the earth also encompasses the sun.

To this astronomical demonstration may be added a physical demonstration of the earth's motion from sir Isaac Newton. It appears from abundant observation, that either the earth turns round the sun, or the sun round the earth, so as to describe equal areas in equal times; but he demonstrates, that bodies revolving about one another according to such law, do of necessity gravitate towards each other. Whence, if the sun gravitate to the earth, action and re-action being still equal, the earth will likewise gravitate towards the sun. But he proves, farther, that two bodies gravitating towards each other, without directly approaching one another in right lines, must both of them turn round the common centre of gravity of both. The sun and earth, therefore, do both revolve round one common centre; but the earth being but a point in comparison with the sun, the common centre of gravity of the two will be within the sun's body, and not far from its centre. The earth, therefore, revolves round a point within the body of the sun, and therefore round the sun. See the arguments for the earth's motion under **EARTH**.

To account for the motion of the planets about the sun, there needs nothing but to suppose an uniform projectile motion, in straight lines, at first given them; and a power of attraction or gravitation, such as we observe in all the great bodies in our system. For a body A (*Plate XIX. Astronomy, fig. 4.*) proceeding uniformly along the line A B, will, by the intervention of the attracting body C, be every moment diverted out of its rectilinear, and bent into a curvilinear path, according to the laws of central forces.

If, then, the projectile motion be perpendicular to a line, C A, drawn from the attracting body C, and its velocity be so proportioned to the force of attraction of A, as that

PLANET.

the centripetal and centrifugal forces are equal, *i. e.* that the conatus to fall to the central body C, in a right line, A C ; and that to proceed in the direction of the tangent, A B, balance each other ; the body will revolve in a circular orbit, A, β , γ , δ , &c.

It is not improbable, that at the beginning this was the state of things ; and that the velocities impressed on the several planets were so combined with their respective masses and distances from the sun at which they were to roll, as that their momenta should counterbalance the sun's attractive force, and be precisely counterbalanced thereby ; whence the primitive orbits must have been perfect circles, from which they do not even now deviate very far. See EXCENTRICITY.

If the planet's projectile motion be not perfectly adjusted to the sun's attraction, the orbit described will be an ellipsis. If it be too swift, the orbit will be greater than a circle, and the nearer focus coincide with the central body ; if too slow, the orbit will be less than a circle, and the farther focus coincide with the central body.

Indeed the form of the planetary orbits does not only depend on the adjustment of the first projectile velocity with the sun's attraction, but also on the direction in which that motion was originally impressed. If that direction were according to the tangent A B, as above supposed, and the central forces exactly balanced, the orbit would be circular ; but if that direction were oblique, in any manner, whether ascending to, or descending from the sun, the orbit of the planet, notwithstanding any adjustment of its velocity to the attraction, would be an ellipsis.

The motions of the planets in their elliptic orbits are not equable, because the sun is not in their centre, but in their focus. Hence they move, sometimes faster, and sometimes slower, as they are nearer or farther from the sun ; but yet these irregularities are all certain, and follow according to an immutable law.

Thus, suppose the ellipsis B E P, &c. (*Plate XIX. Astronomy, fig. 5.*) the orbit of a planet, and the focus S, the sun's place ; A P, the axis of the ellipsis, is called the *line of the apsides* ; the point A, the *higher apsis* or *aphelion* ; P, the *lower apsis* or *perihelion* ; S C, the eccentricity ; and E S, the mean distance of the planet from the sun.

Now the motion of the planet in its perihelion is swiftest, and in its aphelion, slowest ; at E the motion as well as the distance is mean, *i. e.* it is such as would describe the whole orbit in the same time it is really described in.

The law by which the motion is regulated in every point of the orbit, is, that a line, or radius, drawn from the centre of the sun to the centre of the planet, and thus carried along with an angular motion, does always describe an elliptic area proportional to the time. Suppose, *e. gr.* the planet in A, and thence, in a certain time, to proceed to B ; the space or area the radius S A describes, is the triangle A S B : when at length the planet arrives at P, if from the centre of the sun S there be drawn S D, in such manner, as that the elliptic area P S D is equal to that of A S B ; the planet will here move through the arc P D, in the same time in which it moved through the arc A B ; which arcs are unequal, and nearly in a reciprocal proportion to their distance from the sun. For from the equalities of the areas it follows, that the arc P D must exceed A B as much as S A exceeds S P.

This law was first demonstrated by Kepler, from observation ; and is since accounted for by sir I. Newton from physical principles ; and to which all astronomers now subscribe, as of all others that which best solves the planetary phenomena. See CENTRIPETAL Force and GRAVITATION.

From the equal description of areas about the sun in equal times, it appears that the planets move with unequal angular velocities about the sun. Let A P Q (*Plate XIX. Astronomy, fig. 6.*) be an ellipse described about the sun S in the focus, the indefinitely small area, P S ρ , described in a given time, will be constant ; draw P r perpendicular to S ρ ; and as the area S P ρ is constant for the same time, P r varies

as $\frac{1}{S \rho}$; but the angle ρ S P varies as $\frac{P r}{S \rho}$, and, therefore,

it varies as $\frac{1}{S \rho^2}$; that is, in the same orbit the angular

velocity of a planet varies inversely as the square of its distance from the sun. For different planets, the areas described in the same time are not equal, and therefore P r varies as

$\frac{\text{area } S P \rho}{S \rho^2}$, consequently, the angle ρ S P varies as

$\frac{\text{area } S P \rho}{S \rho^2}$; that is, the angular velocities of different plan-

ets are as the areas described in the same time directly, and the squares of their distances from the sun inversely. Hence we obtain a solution of the problem, usually called " Kepler's problem," in the manner stated under the article ANOMALY. For the method of finding the equation of the centre, see EQUATION ; and for the eccentricity, see EXCENTRICITY.

Computation of a Planet's Motion and Place.—As to the periods and velocities of the planets, or the time in which they perform their courses, they are found to have a wonderful harmony with their distances from the sun, and with one another. The nearer each planet is to the sun, the quicker still is its motion, and its period the shorter. The great law they here all immutably observe is, that the squares of their periodical times are as the cubes of their distances from the centres of their orbits.

The knowledge of this law we also owe to the sagacity of Kepler, who found it to obtain in all the primary planets ; as astronomers have since found it also to do in the secondary ones.

Kepler deduced this law merely from observation, and comparison of the several distances of the planets with their periods : the glory of investigating it from physical principles is due to sir Isaac Newton, who has demonstrated, that, in the present state of things, such a law was inevitable.

A planet's motion, or distance from its apogee, is called the *mean anomaly* of the planet ; and is measured by the arc or area it describes in the time. When the planet arrives at the middle of its orbit, or the point G, the distance or time is called the *true anomaly*. (See ANOMALY.) When the planet's motion is reckoned from the first point of Aries, it is called its *motion in longitude* ; which is either mean, *viz.* such as the planet would have, were it to move uniformly in a circle ; or true, which is that with which the planet actually describes its orbit, and measured by the arc of the elliptic it describes.

Hence may the planet's place in its orbit for any given time after it has left the aphelion be found. For suppose the area of the ellipsis so divided by the line S G, that the whole elliptic area may have the same proportion to the area A S G as the whole periodical time in which the planet describes its orbit has to the time given : in this case G will be the planet's place in its orbit.

The mean motions of the planets might be easily determined from their conjunctions and oppositions, if we knew

the places of the aphelia, and the eccentricities of their orbits; for then we might find the equation of the orbit, and reduce the true to the mean place; and the mean places being determined at two points of time, give the mean motion corresponding to the interval between the times. But the place of the aphelion is best found from the mean motion. To determine, therefore, the mean motion, independently of the place of the aphelion, we must seek for such oppositions or conjunctions as fall very nearly in the same point of the heavens; for then the planet being very nearly in the same point of its orbit, the equation will be very nearly the same at each observation; and therefore the comparison between the true places will be nearly a comparison of their mean places. If the equation should differ much in the two observations, it must be considered. By comparing the modern observations, we shall be able to obtain nearly the time of a revolution; and then, by comparing the modern with the ancient observations, the mean motion may be very accurately determined; for any error, by dividing it amongst a great number of revolutions, will become very small in respect to one revolution. Professor Vince has illustrated this method by an example in the planet Saturn, taken from M. Cassini, (*Elem. d'Astron.* p. 362.) and accompanied with the proper explanations. (See his *Elem. of Astron.*) The mean annual motion of this planet is there deduced to be $12^{\circ} 13' 35'' 14'''$, and the mean daily motion to be $2' 0'' 35'''$. Dr. Halley makes the annual motion to be $12^{\circ} 13' 21''$. M. de Place makes it $12^{\circ} 13' 36''.8$. As the revolution thus determined is that in respect to the longitude of the planet, it must be a tropical revolution. Hence, to get the sidereal revolution, we must say, $2' 0'' 35''' : 24' 42'' 20'''$ (the precession in the time of a tropical revolution) :: 1 day : $12^d 7^h 1' 57''$, which added to $29^y 162^d 4^h 27'$, gives $29^y 174^d 11^h 28' 57''$, the length of a sidereal year of Saturn. By this method we may find the periodic times of all the superior planets. The periodic times of the inferior are found from their conjunctions.

The periodic times of the primary planets, copied by professor Vince in his "Elements," p. 113, from La Lande, are as follow: Mercury, $87^d 23^h 15' 43''.6$; Venus, $224^d 16^h 49' 10''.6$; Mars, $1^y 321^d 23^h 30' 35''.6$; Jupiter, $11^y 315^d 14^h 27' 10''.8$; Saturn, $29^y 174^d 1^h 51' 11''.2$; the Georgian, $83^y 150^d 18^h$. The latter is unquestionably erroneous, though copied by many writers, without sufficient attention, from La Lande; as we have shewn in our article *Planetary NUMBERS*. It should have been $84^y 28^d 16^h 55'$. From the tropical period assigned in the article just cited, we deduce the sidereal period, thus: As $365^d.242 : 50.3$ (precef.) :: 30589.352 (trop. per.) : $4212''.5$ the precession in Georgian's whole tropical period: then $4212''.5$ whole precef.

$42''.4$ daily motion = $99^d 8^h 28'$ to be added to the

tropical period for the sidereal: consequently

$$\begin{array}{r} 30589^d \quad 8^h \quad 27' \text{ tropical period} \\ + \quad \quad \quad 99 \quad 8 \quad 28 \text{ arising from precession} \\ \hline \end{array}$$

$30688 \quad 16 \quad 55 =$ the sidereal period: and

$30688.705 = 84^y 28^d 14^h 55'$, the period in years of 365 days, hours and minutes.

N. B. The daily motion of the Georgian in the ecliptic is above taken from La Lande's tables at $42''.4$; but more exactly it is $42''.367$, &c.

For the irregularities in the motions of the primary and secondary planets by their mutual attractions, see *ECLIPIC*,

PLANETARIUM, a machine for representing the motions of the primary planets by wheelwork. This machine differs from an *orrery* in this respect, that it does not profess to exhibit any of the diurnal rotations, but confines its operations to the production of the annual motions alone. These motions may be either *mean* or *equated*; the latter of which were first exhibited, agreeably to the Copernican system, by Huygens's automaton, in 1682; and the former by Roemer's planetarium, soon after. It is not, however, our intention to describe, under the present article, any of the planetary machines which may at the present day be considered as obsolete; but to reserve for our subsequent article an historical account thereof, agreeably to the order of time; and to confine ourselves here to a description of those planetaria of our own time, which either have been adopted, or, from their superior powers, appear to us to merit our public notice, as models for future imitation; to some of which we have already referred from our article *ORRERY*.

Common Planetarium.—It will be seen in our subsequent historical account of *PLANETARY Machines*, that the common planetarium, that presents itself to the eye, as we pass the windows of the mathematical instrument-makers, borrows the numbers of its planetary calculations chiefly from Huygens, and its construction from the planetarium of Roemer, with little or no deviation, except what arises from superior workmanship; and, in some instances, from the addition of the planet Georgian. The common planetarium has its wheelwork represented by *fig. 1. of Plate X. of Planetary Machines*, the effects produced by which may be thus briefly described; viz. *abcd* is a brass frame, similar to the frame of an ordinary clock, in which are contained twelve wheels and pinions, actuating one another respectively in such a way, as to produce the mean motions of the six primary planets, that have been long discovered, of which our earth is one. *AB* is a revolving arbor, pivotted into holes made in the upper and lower plates of the frame, and is made to revolve by means of an endless screw, acting with the lowest wheel of 83 teeth, which is made fast to it, as are also the five other wheels and pinions, with the numbers of teeth specified in the figure. *CD* is an upright stem of steel wire, screwed fast into the lower plate at *C*, and ascending through a large hole made in the upper plate, which it does not fill. The six wheels revolving round this stem have each a separate tube, to the inferior ends of which they are respectively attached; and the tubes are so contrived, that the exterior surface of the innermost forms a stem for the bore of the next largest, till all the six are fitted one within another round the stem of steel, which keeps them in a vertical position, while they revolve separately with different velocities. The arbor *AB*, which receives its motion from the handle, by the medium of the endless screw, is assumed as revolving in a year, which may be either civil, sidereal, or tropical; but whichever be the period assume

PLANETARIUM.

assumed, the pairs of wheels that act together respectively will be so many fractions of that period. Thus, the lowest wheel of 83 teeth, on the annual arbor, will drive its fel-

low 20, with its tube, round in $\frac{20}{83}$ of a year; and the

little arm, that is fixed by friction on its superior end, will perform a revolution round the sun in the same time. In

like manner, the period of Venus will be performed in $\frac{32}{52}$

			D.	H.	M.	S.
Mercury will revolve in	$\frac{20}{83}$	of 365.242, &c. or	88	0	14	24
Venus - - -	$\frac{32}{52}$	of ditto,	or	224	18	20 9
Earth - - -	$\frac{50}{50}$	of ditto,	or	365	5	48 48
Mars - - -	$\frac{75}{40}$	of ditto,	or	684	19	52 19
Jupiter - - -	$\frac{83}{7}$	of ditto,	or	4330	17	30 3
Saturn - - -	$\frac{147}{5}$	of ditto,	or	10738	2	54 43

If these periods be compared with the true periods given under *Planetary NUMBERS*, it will be seen that the mean motions produced by this simple mechanism are far from being accurate, and that the errors, by continual accumulation, will become sensible in a comparatively short space of time; but where general representation only is aimed at, and the respective *times* of the phenomena exhibited by the planetarium are disregarded, this is the cheapest and simplest construction of a planetary machine that has yet been devised; and where its imperfections can be dispensed with, its simplicity is no small recommendation. Still, however, the *true places* of the planets, depending on the *equations* as well as *mean motions* of these bodies, are not the places indicated by this planetarium, supposing its mean motions ever so accurate; nor are the motions of the five recently discovered planets attempted to be exhibited, which they might be by additional wheelwork, without altering the construction of the machine. For the use of those who are satisfied with the representation of mean motions only, we beg leave to suggest the numbers suitable for wheels, that will produce

the revolutions of these five diminutive bodies also. Let $\frac{95}{26}$

be taken for Vesta, $\frac{74}{17}$ for Juno, and $\frac{72}{20}$ for both Ceres and

Pallas, with one tube only for these two pairs; and these wheels, acting in the same way that has been described, will give the mean revolutions with as much accuracy as the present state of our knowledge of the motions of these little bodies will allow. The planet Herschel would require

$\frac{335}{4}$ for its long period, which numbers are impracticable in a small machine; but for this planet a train might be substituted, such as will be described as forming a part of the following machine.

When a planetarium of this common construction is fitted up, its appendages are usually a lunarium and tellurium, separately adapted to the same stand; but in those, the annual and lunar trains are never free from considerable errors.

of the year; the earth in $\frac{50}{50}$, or one year; Mars in $\frac{75}{40}$;

Jupiter in $\frac{83}{7}$; and Saturn in $\frac{147}{5}$; the driving wheels being the denominators of the fractions, and the driven ones the numerators, agreeably to our directions given under the article *Planetary NUMBERS*, for computing the value of wheelwork acting in this simple manner.

If we assume an exact solar year as the period of the first moving or driving wheels, then the fractions will produce the periods subjoined, *viz.*

Planetarium constructed at the House of the Royal Institution.—When the late Dr. Garnett resigned the lectureship of the Royal Institution, and took his astronomical and other apparatus with him into Great Marlborough-street, his successor, Dr. Thomas Young, was authorized by the managers of the institution to procure as good a planetarium for his lectures as he could get for about fifty pounds; this being considered as large a sum as the state of the finances would allow to be expended on one instrument, consistently with the other demands of the apparatus room. The doctor, in consequence of the permission thus given him, examined the shops of the different mathematical instrument-makers for a machine already made, which might be considered as adequate to the illustration of the solar system, in a large and magnificent lecture room. His inquiries, however, were unsuccessful; but having heard that astronomical mechanism was a subject which had occupied the attention of the Rev. W. Pearson, he introduced himself to that gentleman in the autumn of 1801, for the purpose of conferring with him on the subject. The result of this conference was, that, being a proprietor of the Royal Institution from its first establishment, and having consequently an interest in promoting its success, Mr. Pearson agreed to calculate, contrive, and draw a plan for a new instrument, which was accordingly done, and put into the hands of Kenneth McCulloch, an old but ingenious workman employed at that time in the workshops of the institution.

The materials being prepared, the machine was begun in the summer of 1802, and finished in that of 1803, after having been used, in an unfinished state, in the spring course of lectures of the latter year. The arrangement and dimensions of the various parts of the machine are as follow, *viz.* In *fig. 2*, A B C D represent a strong frame of mahogany, well seasoned, and firmly put together, 5 feet 2 inches high, and 2½ feet across; the two upright pieces of which are each in substance 4 inches by 1½, and braced, as seen in the figure; and the cross foot-pieces are each 32 inches long, for the sake of steadiness. Above the cross bar, A B, is another bar E F, 6 inches from the former, which turns upon very strong metallic pivots of five-eighths of an inch diameter,

PLANETARIUM.

diameter, upon brads bearing-pieces, at E and F, which are divided across the centres of their holes, and allow the bar to be taken off and put on at pleasure, by means of a joint, that permits the upper part of each bearing-piece to be turned back. To the shoulders of the pivots are attached the semicircular brads plates, G, G, one-fourth of an inch thick, in which holes are drilled in the horizontal and perpendicular lines, and also at 45° , and at other intermediate angles; into some of which holes two steel bolts, H, H, placed on the bar A B, are inserted, to sustain the mechanism, placed on the moveable bar E F, in any given position. This method of mounting the superstructure gives a degree of steadiness, which could not be obtained from a central joint, and is equally capable of different degrees of elevation. It was found necessary, however, to have a contrivance for either discharging or locking both the bolts at the same time; which contrivance was the invention of K. McCulloch, and answers its purpose completely. The mechanism is simply this: a thick circular plate of brads has an arbor rivetted into it, which passes down through the centre of the fixed bar A B, and has a thumb-piece, I, inserted below, and close to the bar, on a square filed upon its lower extremity, and pinned fast. The circular plate lies with its plane flat upon the bar, with the upper end of the arbor projecting a little; then a diametrical line being drawn across the plate, and divided into two equal parts, a semicircle is drawn from each of the two points, which lie equidistant at opposite sides of the centre, with such a radius, that the diameter of each may be equal to the portion of the bolt which requires to be drawn out. One of the small semicircles is drawn entirely upon one semicircle of the plate, and the other upon the other; after which the two designated small semicircles are perforated in various places, nearly in the shape of an S, and the intermediate solid parts filed away, and rendered perfectly smooth with a burnisher. Each bolt is bent in the form of a half-crank, the remote ends of which are cylindrical, and pass through two cocks fixed on the bar A B; whilst the interior ends are flat, and move each in a dove-tailed groove, made in the wood of the bar under the metallic plate. A steel pin, fixed into each sliding brads bar of the crank-piece, exactly fits, and passes through each semicircular perforation of the circular plate, and completes the contrivance. The manner of applying this mechanism to its purpose is this: as the thumb-piece below the bar, A B, is fast to the arbor of the circular plate above the bar, turning it half round carries the plate along with it half a turn; in consequence of which, the metallic pins, rivetted into the sliding bars of the cranked bolts, are made to approach to, or recede from, the centre of the metallic plate, by reason of their connection with the small semicircular perforations, accordingly as the thumb-piece is turned one way or the other half round; and thus both the bolts are pushed in or out at pleasure by the mere turning of the thumb-piece, and will be kept fast to their places in any situation without an additional security.

Having described the stand of this planetarium, and pointed out the application of its different parts to constitute a whole, we come next to particularize the mechanism which the superstructure is composed of, and to shew the mutual relations of the various portions to each other, in regular succession. The wheelwork, which constitute the ratios of the velocities of the different bodies, claim our first notice.

L M N O, in *fig. 3*, is a frame of strong brads, kept together by four brads pillars, fastened at both ends by thick screws, so that either the upper or the lower plate will take off separately. The length of each plate is $11\frac{1}{4}$ inches, and the breadth 7; and the height of the pillars between the

plates $2\frac{1}{2}$. This frame contains the trains of wheelwork, which produce the respective revolutions of all the primary planets that had been discovered at the time of its invention, including Ceres and Pallas. To shorten the description, we will postpone the dimensions of the wheels, and insert them in a table, where the reader may refer to them after.

At R is an arbor projecting downwards, pivotted into the upper and lower plates of the frame, and revolving, by the application of any power, in the assumed period of an exact solar year. Q Q is an arbor ferewed fast to the lower plate, and, instead of revolving itself, suffers all the wheels which are borne by it to revolve loosely round it. P P is another arbor of the same kind, but longer, and extending 5 inches upwards above the frame, to support the sun and his mechanism. To give the reader a competent idea of the operation and order of the different trains, we will first lay before him the following Table, and then explain it, as it has a reference to the drawing where the same numbers occur.

Order of the Trains.

	Revolving Arbor R.	Fixed Arbor Q Q.	Tubes over P P.
Mercury -	90	22 } 68 }	67
Venus -	113	32 } 29 }	63
Earth -	60	60 } 60 }	60
Mars -	53	56 } 50 }	89
Ceres } Pallas }	21	121 } 60 }	48
Jupiter -	22	111 } 40 }	94
Saturn -	7	124 } 59 }	98
Georgian, or } Herschel }	7	105 } 12 }	67

1st. The wheel of 90 is placed first, or lowest, fast to the revolving arbor R, and drives the wheel of 22 round the fixed arbor Q Q; and along with it the contrate wheel of 68, which is attached to it, and which drives the contrate or last wheel of the train 67, fixed on the longest and innermost tube, to the top of which is fixed the radius vector of Mercury. The communication is made from 68 to 67 by the medium of two similar pinions.

2dly. The wheel of 113 is fixed next over the 90, on the arbor R, and drives its fellow 32 round arbor Q Q, together with 29, to which it is fastened; the latter of which impels the second tubed wheel of 63 round in the tropical period of Venus.

3dly. Four wheels of each 60 teeth are employed in a similar manner, to produce the earth's revolution in an exact solar year; and the last of the four is fastened to the third revolving tube, to carry the annual bar, or radius vector of the earth.

4thly. A

PLANETARIUM.

4thly. A wheel of 53 succeeds on the arbor R, to drive round Q Q the wheel of 56, to which is fastened the wheel 50, to actuate the fourth tubed wheel of 89 in the tropical period of Mars.

5thly. A small wheel of 21 is next mounted on the arbor R, to drive 121 round Q Q, and with it 60 as a fellow for 48, to which is attached the fifth revolving tube, which carries both Ceres and Pallas round in the same period; the difference of their respective velocities being not yet sufficiently ascertained to require a difference in the wheelwork.

6thly. The small wheel 22 comes next on the arbor R, and drives 111 round Q, and also with it 40, as a fellow for the sixth tubed wheel of 94, with which is connected the radius vector of Jupiter.

7thly. The long pinion of 7, which is cut in the solid part of the arbor, is common to both Saturn and Georgian, and drives the wheel 124 round the fixed arbor Q Q, and with it 59, as a fellow, to impel the seventh tubed wheel of 98 in Saturn's period.

Lastly: The said pinion of 7 also drives, by its upper end, the wheel 105, and along with it the perforated pinion 12, which makes the wheel 67 together with the eighth tube revolve, and conduct on its upper end the radius vector of Herschel.

This is the *order* in which the wheels stand when they act; and their number might have been diminished one half, if accuracy in the calculations had not been considered as a primary object. But to obtain a great degree of accuracy,

the numbers that constitute the ratios of a year necessarily run high, and render it unavoidably requisite to break the high simple fractions into compound ones of fewer figures, but of the same value; or, which is the same thing, it became expedient to substitute, in the most convenient manner, a train of wheels for each planet, instead of a simple pair, where great accuracy must have been out of the question. By this adoption, it will be seen in the subjoined table of the powers of the wheelwork, that a greater degree of accuracy is attained than had perhaps ever been before accomplished; and that not merely in one, but in all the revolutions of the different primary planets.

But before we give the tables of dimensions and powers of the wheelwork, it will be proper to observe that *fig. 4*, which is an end-view of the frame, represents three brass bridges, with tubes fastened to them, to be interposed between the revolving tubes, in order to bear the weight of the machinery, and to take off the friction, which would otherwise have been too considerable to be dispensed with. The first bridge, 1,1, spans over the tubed wheel of Mercury, and has its tube next in length to that of Venus, that a motion may be derived therefrom to the sun's axis. This bridge is screwed to the upper side of the lower plate of the frame. The second bridge, 2,2, with its tube, is placed over the tubed wheel of the earth, and is fastened by screws upon the lower plate, like the first bridge; and the third bridge, with its tube, lies between the tubed wheel of Saturn and that of Jupiter, and is supported by the upper plate of the frame, and is therefore inverted.

Powers of the Wheelwork.

But

PLANETARIUM.

But notwithstanding the mean motions of all the planets are represented by this wheelwork with extreme accuracy, yet, if they were all *equable*, the true apparent places of the planets would not be accurately exhibited, except at the aphelion and perihelion points of their orbits, where the aggregate of all the increments and decrements of motion balance one another, *i. e.* where there is no equation of the centre, or prosthaphæresis; for all the planets, that have any considerable excentricity in their orbits, continue many days longer in one half of their orbit than in the other: for instance, Mercury, as we have said in another place, continues about $55\frac{1}{2}$ days in one half of its orbit, and only $32\frac{1}{2}$ in the other; and even in the earth's motion, the difference amounts to 7.8 days, where the excentricity of the orbit is very small. Hence arises the necessity of some mechanical means for accelerating and retarding, alternately, the various motions of the different heavenly bodies in the respective parts of their orbits, that the heliocentric places may accord, from day to day, with the places calculated in the Nautical Almanac, and in White's Ephemeris; and also that the days of opposition and conjunction, the times of the stations, and the respective durations of the apparent direct and retrograde motions, may be all accurately indicated; none of which, a machine representing only mean motions can have any pretensions to effect, however accurately its wheelwork may be calculated. Likewise, to make the geocentric appearances what they are in the sky as seen from the earth, and what they are calculated to be in the Nautical Almanac, and in White's Ephemeris, the *variable distances* must be also represented, otherwise the greatest elongations of Mercury, and the annual parallaxes of the superior planets, would always remain the same, as though their orbits were in concentric circles round the sun.

To effect the two requisites of varying velocities and of varying distances, the two following contrivances are adopted, which, without adding much to the complexity of the mechanism, completely produce both the desired effects, and consequently all the phenomena dependent upon them: first, the tubed wheels of those planets, which have considerable excentricity, and consequent variation of motion, have their teeth cut in so peculiar a manner, that the size of them varies gradually throughout the whole of each semicircle, so as to throw just so many teeth more into one half of the wheel than into the other, as are proper for producing *one half* of the grand equation of each planet; and, secondly, a small arm suspended at the extremity of each radius vector, and revolving with the planet in a retrograde direction, by means of an appended weight, shews both the *variation of distance*, and also the *other half* of the grand equation. The weight, too, is adjustable, so as to make the aphelion and perihelion points fall in their proper places in the ecliptic; and what is a wonderfully lucky coincidence of circumstances, the same mechanism, that answers these purposes, preserves, moreover, the parallelism of the axis of every planet, as well as of the ring of Saturn. The proportion between the radius vector and short arm of each planet is as the radius of the planet's orbit to its excentricity; the radius *plus* the excentricity being equal to the aphelion distance, and the radius *minus* the excentricity being equal to the perihelion distance. See *EQUATION Mechanism*.

It would exceed the limits of this description, were we to introduce here the proper directions for cutting the tubed wheels in the requisite manner. Suffice it, therefore, to say, that the inventor lent to the institution a cutting engine of his own, on the plate of which he had previously divided all the required circles in such a way, as would necessarily divide and cut the wheels in a proper manner by its ordinary operation, without any extra skill in the workman. The danger of

inaccuracy, in the execution of this otherwise extraordinary process, was thereby obviated; and he had the satisfaction of seeing a practical difficulty vanish, which might have proved insuperable to the mere theorist. Care, however, was previously taken to ascertain that the largest and smallest tooth of every wheel were capable of being acted upon by the mean-sized teeth of the driving wheel, with which each tubed wheel had to co-operate; but it was found that the disparity between the largest and smallest teeth of Mercury's tubed wheel was too considerable to admit of the same method of cutting the teeth, that would apply to the rest: hence, had no other practicable method of effecting half the equation of this planet presented itself, the motion could not have been made perfect enough for the requisite purpose; but fortunately a second method occurred of producing the required degree of acceleration and retardation, and that without any inequality at all in the teeth, which was that of placing the tube as much out of the centre of the wheel as is equal to the excentricity of the orbit, the radius of the wheel being taken as its radius. The wheel consequently was made a contrate one, and takes its motion from its fellow, by the interposition of two pinions placed at opposite ends of an horizontal arbor; which arbor is sustained by the lower plate of the frame, and pivotted into a cock at each end. The pinion which drives the excentric contrate wheel was, therefore, required to be longer than double the excentricity of the wheel, that it might not escape its teeth: likewise the spaces of the wheel were required to be filed with an equaling file, held in a direction pointing not to its centre, but to the excentric point in which the tube is fixed, in order that, during its action, the friction might be as little as possible.

This method of producing unequal motion, we have before said, was first applied by Huygens in his automaton planetarium; but we have shewn (under *EQUATION Mechanism*) that he mistook the effect, by supposing that the *whole* equation would be thus produced, whereas, in fact, only *one-half* of it is effected, which is what the inventor's purpose requires.

As the exact periods and other data of the orbits of the two newly-discovered planets, Ceres and Pallas, were not ascertained with sufficient accuracy, their tubed wheel was cut, *pro tempore*, into equal teeth, as was also that of Venus, by reason of her excentricity being too inconsiderable to require notice; but the other planets have the teeth of their tubed wheels so distributed in the two semicircles, which are bisected by the line of the apides, that one semicircle of each contains more teeth than the other, in the proportion expressed in the annexed table.

TABLE of the Teeth contained in the respective Aphelion and Perihelion Semicircles.

PLANETARIUM.

The above table will assist the workman in estimating the perfection of the cutting by an engine with appropriate unequal divisions; for when a diametrical line is drawn from the aphelion to the perihelion points marked on each wheel, each of those semicircles will contain the same number of teeth, notwithstanding another line bisecting this at right angles will contain those proportions which are expressed in the table; an examination of this kind will be a check upon the workmanship.

The tubes move round one another without the least shake, and extend above the frame unequally, the innermost, or longest, being $6\frac{1}{2}$ inches long, and $\frac{1}{10}$ bore, and the outermost, or shortest, $\frac{3}{4}$ ths of an inch long, and $1\frac{1}{4}$ bore; they go within one another, as in the common planetarium, in order that all the radii vectores may be borne by the upper ends of their respective tubes.

Fig. 5. exhibits to view the under face of the lower plate of the frame, in which the same letters denote the same parts as in fig. 3.

This lower plate of the frame, that contains the wheel-work, is bedded into and screwed fast to the upper surface of the moveable cross-bar of mahogany E F, so that the tubes may be exactly over the middle of it; and the upper plate of the said frame is bedded into, and made fast to a circular mahogany board of forty-six inches diameter, to which it is attached by several strong brass bars, which are screwed both to the brass frame and to tapped brass nuts let into the circular board below: the tubes project through a central hole, made in the large circular board, just large enough to admit them to pass through it: the frame and circular board, therefore, may be put into either a horizontal or perpendicular direction, or into any intermediate elevation, in any of which positions it will be kept steady by the bolts H, H. The circular board is composed of many separate pieces of wood, fitted together in such shapes, and in so compact a manner, as to prevent its warping, in doing which, the contriver, M'Culloch, shewed great ingenuity: this circular board is painted blue on its upper surface, and has a large ecliptic mounted upon it by means of twelve perforated pillars of blackened wood, through which metallic rods pass and screw at both ends, above into fixed nuts under the ecliptic circle, and below into loose nuts under the circular board, so that the ecliptic may be mounted or dismounted at pleasure. This ecliptic circle, which is three feet and a half diameter within, and four feet and a half across the extremities, has the characteristic animals, or supposed animals, beautifully painted in oil colours on a black ground, and surrounds all the radii vectores, and therefore must be considered as the Earth's orbit projected into the heavens beyond the planetary system; it serves admirably to rectify the planets by, and also to ascertain all their heliocentric and geocentric places, at the same time that it adds greatly to the grandeur of the tout ensemble appearance of the machine, when in an erect position before an audience.

The radii vectores, short arms, weights, and the other visible parts of the mechanism, for the sake of effect, are also painted blue, except the ivory balls which represent the planets, the contrast between which and the blue ground behind, gives the semblance of real motion, without mechanical means, to an eye placed in front, at the remote part of the theatre.

A spectator viewing the planets obliquely, will moreover perceive them project beyond the ecliptic in one-half of their orbits, and retire within it in the other, which motion constitutes their variation of latitude, or deviation from the

plane of the ecliptic; another effect which is not usually shewn by a planetarium; and the quantity of latitude north or south of each planet is indicated by small fixed hands pointing to the respective small revolving plates borne by the projecting stems of the radii vectores; which plates are silvered, and properly divided and figured by an engraver. The planets Mercury, Ceres, Pallas, and Mars, having no secondaries, have their latitudes shewn by a bend on the exterior ends of the projecting stems of the radii vectores, round which bent parts the small arms revolve, so as to make their respective angles with the plane of the ecliptic. This method of shewing the latitude is very simple, but requires the small arms to be elongated beyond what they would have been, when moving in the plane of the ecliptic, in the same proportion that the hypotenuse of a right-angled triangle is to its base, the included angle being subtended by such a perpendicular line as will be a sine to the requisite degrees of heliocentric latitude, at the distance from the sun of the radius vector of each planet.

The stems on which the arms and weights revolve screw into nuts under the ends of the radii vectores, by means of which the inclination of the bent ends may be set to any particular situation, so as to make the nodes fall in their due places with respect to the ecliptic; and by being thus adjustable, the stems may be easily rectified for the motion of the nodes at the end of every century, or longer period of time. The idea of bending the ends of the stems was suggested by Dr. T. Young, and affords a simple method of effecting the latitude of all the planets in question, except that of Pallas, the latitude of which is too great to be altogether represented by such a limited arm as the other parts of the mechanism will allow: the planet Venus having considerable latitude, and very little eccentricity, required a different contrivance, as did also those planets which have secondaries; otherwise the planes of the orbits of the secondaries would have been turned into various angles, as they regard the ecliptic, in different situations of the radii vectores. The application of an inclined circular plate promised best to produce the desired effect of raising and depressing Venus, and the system of Jupiter, Saturn, and Georgian or Herschel, and were therefore adopted. The action of the inclined plate on the stem of the planet, is caused by a notch on the stem resting against the edge of the fixed plate, while the small arm, revolving round the said plate, carries the stem round it; by which means the planet carried by the stem projects and recedes alternately, as much as one edge of the circular plate is more prominent than the other. This effect is not easily comprehended from a simple verbal description, but is readily perceived in the machine.

With respect to the distances of the planets from the sun, it was impossible to observe the exact proportions without making the sun's ball very minute, and Mercury close to it, or else Georgian at an immense distance from the sun; in which case the machine must have been a horizontal one, and the ecliptic circle in another situation. It was, therefore, determined, that though the exact proportions of distance could not be preserved, yet the lengths of the radii vectores should be in due proportion, as far as to Mars inclusively, upon a scale that made the Earth five inches from the sun, and that the longer radii vectores should be an exact fractional part of their due lengths, rather than have no proportion at all, as is the case in the common planetaria.

These lengths of the radii vectores, and the corresponding lengths of the short revolving arms which represent the respective eccentricities proportional to the lengths of the radii vectores, are expressed in the annexed table.

TABLE

PLANETARIUM.

TABLE of Distances and Excentricities of the Planets in the Planetarium.

Planets.	Mean Distance from Sun in Inches.	Ratio to the Truth.	Short Arms.
Mercury -	1.94	1 : 1	0.38
Venus - -	3.61	1 : 1	0.025
Earth - - -	5.0	1 : 1	0.08
Mars - - -	7.61	1 : 1	0.69
Ceres - - -	10.35	3 : 4	0.87
Pallas - - -	10.35	3 : 4	2.59
Jupiter - -	13.0	1 : 2	0.62
Saturn - - -	15.9	1 : 3	0.88
Georgian or Herschel }	19.19	1 : 5	0.91

The radii vectores have each a counterpoise, and are fastened to the ends of their tubes by a clamping-piece of brass attached to each of them by pins, and made so as to be tightened by a screw, which draws the ends near together.

The inclination of the orbits are proportioned thus: viz.

The inclination of	{	Mercury - - -	=	7° 0' 0"	at	1.94	}	distance is subtended by	{	0.237
		Venus - - -	=	3 23 35	at	3.61				0.213
		Mars - - -	=	1 51 0	at	7.61				0.247
		Ceres - - -	=	10 37 56	at	10.35				1.92
		Pallas - - -	=	35 0 42	at	10.35				6.3
		Jupiter - - -	=	1 18 56	at	13.0				0.296
		Saturn - - -	=	2 29 50	at	15.9				0.69
Georgian, or Herschel }	=	0 46 20	at	19.19	0.256					

It must be observed, that the subtending lines here calculated must be doubled to shew both north and south latitude; therefore the quantity of rising and falling, or of projecting and retiring with respect to the plane of the ecliptic, must be double the quantity above expressed.

The sun's mechanism remains yet to be explained, which,

as we have seen, consists of the train $\frac{19}{137} \times \frac{25}{62}$ of Mer-

cury's tropical revolution = $25^d 10^h 0^m 0^s.223$; the motion is communicated thus; - on the top of Mercury's long tube is fastened the large contrate wheel of 137, which impels the pinion of 19, to which is attached the wheel of 62, which drives the small wheel of 25 on the sun's axis round in the specified period, which does not vary a quarter of a second from La Lande's last determination of the time of a rotation, as it regards a fixed point: the three last wheels with their bearing-pieces are borne by a small brass bar fastened to the top of the fixed stem of $7\frac{1}{2}$ inches long, round which Mercury's tube revolves, which piece of mechanism is seen in its proper place near the upper P, in fig. 3, under the sun.

It must, however, be recollected that Mercury's tube does not revolve *equally*, by reason of its being fastened into

a point, as nearly as may be, $\frac{1}{3}$ th of the wheel's radius out of its centre, and therefore a compensation was necessary to equalize the motion of the sun round the axis, which otherwise would have been quicker on some days than on others: this compensation was very easily effected, by placing also the large wheel of 137, as nearly as may be, $\frac{1}{3}$ th of its radius out of its centre, but in the semicircle diametrically opposite to that of Mercury at the lower end of the tube, in order that when the aphelion tooth of Mercury's wheel is in action with its pinion, the perihelion tooth of 137 may actuate its pinion of 19, which, by reason of the excentricity of 137, must be a long pinion: thus, when an acceleration takes place in the wheel of Mercury, a retardation takes place in that of the sun, and *vice versa*, by which means the motion of the sun round his axis becomes equable, the increments of one wheel's motion balancing the decrements of the other.

The inclination of the sun's axis to a line perpendicular to the plane of the ecliptic is $7^\circ 16'$, and it points always to $17^\circ 53'$ of Virgo; hence the direction in which a solar spot will move, whether ascending, descending, or horizontal, to an eye situated at the Earth, will be seen to depend upon the Earth's situation in her orbit, as she has reference to the direction of the sun's axis. The secondaries have no motions by wheelwork, because such motions would have added greatly to the complexity of the machinery, as well as have enhanced the expence.

The appendages of this planetarium are these; 1. A light rod is adapted to the Earth's stem, and extends to either of the interior planets, to shew the retrogradations, stations, and direct motions. 2. A rod with a fiducial edge, containing the mean distances marked, and having a curve piece at the remote end, applies to the sun's stem, by means of a downward bend, which rod, laid on the ecliptic circle, level with the centre of the sun, and extending with its opposite end to the sun, will serve to place the planets in their due heliocentric places in the rectification, and also to ascertain the places on any given day after they have been in motion: this rod will also serve the lecturer to point with to any part of the instrument during the lecture. 3. The handle, which is in an erect position, behind the circular wooden board, when the ecliptic is erect, has a single endless screw, seen in fig. 5, at S, acting with a wheel of 52 strong teeth, placed on the lower end of the annual arbor R, without the frame, so that one turn of the handle corresponds very nearly to a week. A large spiral face is also behind the circular board, removed from the brass frame LMNO, by the interposition of the moveable cross bar of mahogany EF, to which it is screwed with its centre open for the annual arbor to pass through, which carries the annual index: to the end of the annual arbor is also fixed a pinion of ten, driving a wheel of 100 round in ten years, which wheel has another pinion of ten attached to it, to drive a second wheel of 100 round in 100 years, the use of which two wheels, not seen, is to indicate the year in each succeeding century, for which the instrument at any time stands rectified, which addition assists the memory, and saves the trouble of frequent rectification. The spiral of the said face is quadruple, and is divided into the months and days of the year, taking in the 29th of February in every fourth year, like the spiral we described under our article ORRERY. The wheels for indicating the year and century lie behind the plate of the large spiral, and take their motion from the projecting arbor at R, and the figures are read through holes cut in the said plate, the hands of which are secured by screws, when set to their places. The rectification of this planetarium for a given time is attended

PLANETARIUM.

attended with some trouble, and therefore, when rectified, should be guarded against the eye of curiosity. As the wheels have several of them unequal teeth, it is necessary that the aphelion teeth of each should be in action, when the planets are respectively at the aphelion points of their orbits, and that the arms should be made fast when properly placed: when the wheelwork was first put together, the wheels were marked for their places of action, to correspond to the 1st of January 1800; and if these marks be brought in contact for that time, and the arms be put to the corresponding heliocentric longitudes, turning the handle till the hands shew the present time, will always be the surest, as well as easiest way of rectifying: but should the marks be effaced, each planet's distance from the aphelion must be calculated for the time, and both the wheel and arm be placed accordingly in succession. In order to disengage the screw S at any time from the annual wheel of 52 teeth, the cross bar T U (*fig. 5.*) is pushed in, or drawn out, as the case may be, and while it moves in a parallel direction by means of its longitudinal openings, admitting the pin W and screw X to guide them, the diagonal opening V, taking the pin Y of the cock that holds the screw, draws it out of, or pushes it into the wheel's teeth, accordingly as the bar is moved from T towards U, or from U towards T, in either of which situations it may be fixed by the nut of the screw X. The arbor of the screw S is squared, so as to admit of the handle at either end of it, as may be most convenient to the lecturer's assistant, who, standing behind the machine to turn the handle, is concealed from the audience.

The new Planetarium for equated Motions, by the Rev. W. Pearson.—Under our article ORRERY, when describing the new orrery for equated motions in three parts, we referred the reader to our present article for that portion of it, which constitutes the planetarium at present under our consideration. This planetarium, being contrived to exhibit the mean motions, the grand equations, and all the variations of distance, as well as of velocity, in the different parts of the respective orbits, demanded a new construction, and consequently new calculations. We have already described the principle by which equated motion is produced in this machine, under the title EQUATION *Mechanism*, near the end of that article; and have also given an example, under our *indirect method of approximation*, (see *Planetary NUMBERS*,) of the mode of calculating wheels for the motion of Venus, when one of those wheels is not in a stationary situation, which mode applies to all the trains of this planetarium, except those of the sun and of Mercury; we must, therefore, request the reader to recur to those two articles, and to make himself master of them, before he proceeds to examine the calculations and contrivances that we now propose to present to him.

Fig. 1. of *Plate XI.* of *Planetary Machines*, presents an elevation of all the wheelwork of their proportional dimensions, and in the state of action; and *fig. 2.* gives a plan of the arm or radius vector of Saturn, which will suffice to explain all the other arms. In *fig. 1.* A B is a section of an ornamental table or stand, broken into two parts at the side A, for the purpose of bringing it into the plate; and the legs are omitted for the same reason, but may be conceived to extend downwards the requisite quantity, as represented in *Plate V.* which gives a perspective view of a similar table. Below A and B, a section of the ornamented rim of the table is seen; at C is the handle turning the horizontal arbor, C D, round in seven days, and the exterior end of this arbor carries a hand to indicate the seven days of the week, on an engraved plate attached to the side rim of the table under B.

This period of seven days is assumed as the basis of all the planetary calculations, and therefore all the motions must be traced in succession from this first moving arbor. The inner end of this horizontal arbor is supported by the cock G, screwed to the bottom of the table, and carries a pinion of 18 teeth, that drives a contrate wheel of 61 teeth placed under it, apparently without support: the axis of this contrate wheel is a piece of steel wire, nicely polished, which ascends through a thick brass tube, as high as F, under the sun, and is retained within it, by a screw entering its squared end at F. This thick tube of small bore has a shoulder-piece attached to it, which rests on the middle of the table at H, and the lower end of it is held by a large tapped nut under the table, above the wheel of 61 teeth. By these means the tube stands firmly in a vertical direction, and bears the superincumbent weight of all the wheels and arms, both which are always exposed to view. At F, on the superior squared end of the axis, or wire E F, is fixed fast, by the screw we have mentioned, the pinion 28, which drives another pinion 30 round on the inferior end of the sun's stem: the period of

this revolution, or rather rotation, is $\frac{61}{18} \times \frac{30}{28}$ of 7 days =

$25^d 10^h 0^m 0^s$, which is the period last determined by *Lalande*. To the pinion 28 is attached a wheel under it of 53 teeth, by means of a connecting piece of brass tube that surrounds the steel wire, which wheel rests on the top of the brass tube, which in future we shall call the central stem, as though it were solid. The wheel of 53 drives another of 35, supported by a horizontal bearing piece that supports the sun's stem at its opposite end, as seen in the figure; and this bearing piece has a short tube folded into it below, through which the arbor of this wheel of 35 passes, and receives a pinion of 13 at its lower end; the axis or arbor of pinion 13, and of wheel 35, is detained in a vertical position by a screw above the centre of wheel 35, but so as to allow the wheel and pinion to revolve without any shake of the arbor within the tube: this pinion of 13 drives a wheel of 73 teeth, or rather a ring with the teeth cut on the inner edge, for the sake of making its motion proceed in the requisite direction, and the period of its revolution is

$\frac{61}{18} \times \frac{35}{53} \times \frac{73}{13}$ of 7 days, or, which is the same thing, in $\frac{28}{30} \times \frac{35}{53} \times \frac{73}{13}$ of $25^d 10^h$, namely, in $87^d 23^h 14^m 36^s$.

The ring we have described, therefore, carries the stem of Mercury, and is screwed to a circular plate of brass, the centre of which is fitted so as to turn easily round the central stem without shake. If the mean motion only of Mercury had been wanted, the wheels we have described would have been the whole that the planet would have required, but the equation of the centre required some additional wheels, which are thus applied; a little wheel of 30 teeth is attached to the sun's bearing piece, by the interposition of a piece of brass tube, and therefore has no motion; another similar wheel lies on the circular plate of the ring and acts with it, while the axis of this second wheel of 30 passes through the plate, and takes another similar wheel, under the plate; while the plate and ring therefore revolve together in Mercury's period, the second and third wheels, of each 30, revolve together just once by means of their connection with the first or fixed wheel, round which they are carried; then this motion is communicated to a fourth similar wheel of 30, fixed to the lower end of Mercury's stem, which wheel gives Mercury a rotation on his axis in each revolution; but the stem of Mercury is cranked, as seen in the figure, and as

PLANETARIUM.

the parallelism of the crank is preserved during its whole revolution, the distance of the planet will vary constantly, as well as its velocity, in the manner that has been explained under the article EQUATION *Mechanism*, above referred to. When the horizontal part of the crank is equal to double the eccentricity of the orbit, the equation will be properly represented, but the distances will be better exhibited when the said piece is equal to the simple eccentricity; there are, therefore, two holes drilled and tapped in this piece, to suit either condition, but the nearness of the planet to the sun will not allow the introduction of the correction, which most of the other planets have got, as will be presently explained.

Hitherto the usual mode of estimating the value of a common train of wheels has been adhered to, because the two trains that we have examined are so placed, as to act in the usual way in stationary positions; but henceforth we shall have to consider trains, in each of which a certain portion is placed on and carried round the sun by the very arm that is put into motion. In this construction, for a reason that will appear presently, the system of concentric tubes, contrived by Roemer, and used in the common planetarium, is impracticable, unless as many fixed tubes could be introduced between them alternately, as there are revolving ones; the motion of each inferior planet is therefore transmitted to the next superior, beginning with Mercury and ending with Georgian, so that each calculation is necessarily that of a ratio between the periods of every pair of contiguous planets taken in succession. In calculating those ratios the author had two choices, namely, of the *periodic*, and of the *synodic* revolutions; one of which, as we have shewn under the head NUMBERS *for Synodic Revolutions*, is easily convertible into the other: if the periodic revolutions had been preferred, the wheelwork must necessarily have been placed on cocks, bridges, or in other *permanent* situations; but when synodic periods are chosen, some of the wheels will require to be placed, or at least will admit of being placed on *moveable* supports; the latter revolutions were thence chosen, in order to do away the necessity of cocks and bridges, and the numbers calculated to produce synodic revolutions, by the *mode* in which they are used, produce the periodic revolutions, after an allowance is made for the precession of the equinoxes. Thus, if the tropical period of Venus be to that of Mercury as 224^d.69847: 87^d.96579, we shall find, by one of the methods of determining *planetary* NUMBERS, that these periods are to each other as 1553: 608 very nearly; but the numbers for the synodic period are here required; therefore let 608 be taken from 1553, and let the remainder, 945, be substituted for 1553, as one of the products for two wheels, while 608, the other product, remains unaltered; then while

$\frac{1553}{608}$ of Mercury's tropical revolution is equal to that of

Venus and also $\frac{608}{1553}$ of Venus's tropical period equal to

that of Mercury, absolutely considered, it will be found that $\frac{608}{945}$ of the tropical period of Venus will be the *synodic* or

relative period of the two planets, Mercury and Venus, from conjunction to conjunction, namely, 144.54 &c. days, which time very nearly corresponds to the period given in our table of mean synodic revolutions, inserted under the title NUMBERS. Now the factors composing the ratio

$\frac{608}{945}$ are $\frac{38 \times 16}{15 \times 63}$, or in the form of a train inverted, (be-

cause the motion is given by Mercury,) $\frac{15}{38} \times \frac{63}{16}$, or otherwise $\frac{63}{16} \times \frac{15}{38}$; but the latter portion is equal to $\frac{30}{76}$ and accordingly we find $\frac{30}{76} \times \frac{63}{16}$ the train adopted in the plane-

tarium before us. The wheel 76 revolves along with Mercury's ring, to which it is made fast, and drives a pinion of 30, revolving on a pin, or stud, at the posterior end of Venus's arm, by which it is carried; then a pinion of 16 made fast to the said pinion of 30 acts with the wheel of 63, by the intervention of a pinion 14, the office of which is merely to change the direction of motion, without affecting the velocity. The wheel of 63, however, though connected with the train in the way we have mentioned, is made fast to the central stem, by close fitting, and therefore does not move, but by its resistance causes the arm of Venus to move instead, thereby making the pinion of 14 revolve round it, and producing an effect on the motion of the train equal to what would have been produced by one entire revolution of itself. In this way the calculations made for synodic revolutions in all the other trains, produce the requisite tropical periods of all the remaining primary planets, agreeably to the table of wheelwork which we have subjoined, for the sake of abbreviating our description.

Again, the wheel 126, under the arm of Venus and made fast to it, drives a pinion of 26 and its attached pinion of 32, both which revolve on a stud on the earth's arm; and the intermediate pinion 13, being refitted by the fixed wheel of 97, revolves round it and carries the earth's arm round the sun in a solar year, as it regards the ecliptic; but as it regards Venus, in the proper synodic period of 583.9 &c. days. On the earth's arm are carried the wheels and pinions for preserving her parallelism and also for producing the moon's period, both which are effected with great accuracy: just above the said arm the wheel of 107 is fixed to the central stem, and by its resistance gives motion to the wheel 62, which again impels another wheel of 107 in a contrary direction, thereby producing true parallelism; in the mean time wheel 86, made fast to wheel 62, revolves with it on a stud, and, through the medium of a small wheel of 32, for changing the direction of motion, impels the pinion 12, with which the moon is connected. The lunation thus occasioned

is $\frac{62}{107} \times \frac{12}{86}$ of 365.242, &c. = 29^d 12^h 44^m 0^s.4. At a

small distance below the earth's arm, and fast to it, revolves the wheel 142, impelling the pinion 28 and with it the pinion 30, resting together on a stud in the arm of Mars; while the intermediate pinion of 13, refitted by the fixed wheel 134, draws the arm of Mars round in his proper period. To the arm of Mars and not far under it is made fast the wheel 166, which impels the wheel 53, and with it the 34 attached to it, round a stud on the arm of Pallas, while the intermediate pinion 15, opposed by the fixed wheel of 154, pulls the arms of both Pallas and Ceres round with the same velocity in a period which was calculated to be a mean between the two, and as far as we yet know, is not much different from either. At the time when these periods were calculated (1806), those of Juno and Vesta had not been ascertained, nor had Vesta been discovered; but room was left during the progress of the work for their introduction, and arms were since inserted on the same tube that carries the other two arms, which may be adjusted by hand occasionally when their places are required for any particular purpose; but when the period of those little bodies are finally settled

PLANETARIUM.

they may be also represented by appropriate mechanism. Below the four arms of the little planets, and fast to their common tube, revolves the wheel 182 in the common period of Pallas and Ceres, actuating the small wheel 40 and its attached pinion 17, carried by a stud on the arm of Jupiter, while the interposed pinion of 25, taking hold of the fixed wheel 122, conducts the arm round the sun in its proper period. Again, beneath Jupiter's arm, and attached to it, revolves the wheel 126, actuating the wheels 43 and 41 round a stud on Saturn's arm; and the small pinion 11, taking the teeth of both the small wheel 41 and of the large fixed wheel 178, conducts Saturn's arm round in his due period. And, lastly, the wheel 129 under Saturn's arm moves fast to it, and drives the small wheels 39 and 28, made fast together and placed on a stud on Georgian's arm, while the intermediate pinion 20, taking the teeth of the fixed wheel 171, thereby conducts Georgian's arm through its revolution by a slow motion in its requisite time. Thus each planet, except the little ones lately discovered, from Mercury downwards, has got a train of a moveable wheel, two small wheels united together, a single intermediate pinion, and a fixed wheel; and our explanation of the mode of action of the train of Venus, will apply individually to

all the rest. Before the wheelwork was put together, it was apprehended that there would be a considerable portion of time lost in the transmission of motion through all the trains from Mercury to Georgian, when the handle should have commenced its operation, which apprehension constituted the inventor's principal objection to the theory of the construction, before the machine was put into hand; but Fidler, the workman, being forewarned of this probable imperfection, laid all his teeth so deeply into one another, that no one wheel has any shake, and the moment that the handle commences its motion, all the wheels of the machine are immediately in action, and consequently all the planets begin to move, as nearly as can be perceived, at the same time. Perhaps a more complete structure of wheelwork was never put together, to answer a similar purpose, and yet the handle moves with freedom and without any sensible jerks. Many of the wheels were at first calculated to have smaller numbers of teeth, but the nature of the construction required that the fixed wheels, and consequently some of the moving wheels, should be large, in order to guide the arms of mean motion with uniform steadiness, as well as to render all the motions contemporaneous at their commencement.

A TABLE of Tropical Periods produced by the Synodic Trains.

		D.	H.	M.	S.
The handle is assumed to revolve in	-	-	-	-	7 0 0 0
Sun's axis	$\frac{61}{18} \times \frac{30}{28}$ of seven days	-	-	-	25 10 0 0
Mercury	$\frac{61}{18} \times \frac{35}{53} \times \frac{73}{13}$ of ditto.	-	-	-	87 23 14 36
Venus	$\frac{30}{76} \times \frac{63}{16} = \frac{945 + 608}{608} = \frac{1553}{608}$ of Mercury's period =	-	-	-	224 16 41 56
Earth	$\frac{26}{126} \times \frac{97}{32} = \frac{1261 + 2016}{2016} = \frac{3277}{2016}$ of Venus's period =	-	-	-	365 5 48 39
Mars	$\frac{28}{142} \times \frac{134}{30} = \frac{938 + 1065}{1065} = \frac{2003}{1065}$ of the Earth's period =	-	-	-	686 22 17 11
Pallas and Ceres	$\frac{53}{166} \times \frac{154}{34} = \frac{4081 + 2822}{2822} = \frac{6903}{2822}$ of Mars's period =	-	-	-	1680 7 43 23
Jupiter	$\frac{40}{182} \times \frac{122}{17} = \frac{2440 + 1547}{1547} = \frac{3987}{1547}$ of Pallas's period =	-	-	-	4330 14 28 28
Saturn	$\frac{43}{126} \times \frac{178}{41} = \frac{3827 + 2583}{2583} = \frac{6410}{2583}$ of Jupiter's period =	-	-	-	10746 20 52 36
Georgian	$\frac{39}{129} \times \frac{171}{28} = \frac{2223 + 1204}{1204} = \frac{3427}{1204}$ of Saturn's period =	-	-	-	30589 7 18 58
Moon	$\frac{62}{107} \times \frac{12}{86}$ of 365.242 &c.	-	-	-	29 12 44 0

In computing the exact value of each of those periods in succession, we have had no reference to the true periods as given in La Lande's Tables, but have deduced each period from that of the preceding planet, as produced by the wheelwork, which is the only true method of appreciating the real values; and if these periods be compared to those of the planetarium made at the house of the Royal Institution, or indeed to those of any other machine, they will be found to claim a preference, as to accuracy, in many of the periods, and are inferior in none, except in those of the Earth and Jupiter; but in all the other planetaria the earth is assumed as having its period exact, and is made the standard by which the others are guided, and therefore re-

quires no calculation for particular wheels; whereas in this machine all the periods are derived from the motion of the weekly handle; and with respect to Jupiter, when the periods of Juno and Vesta are introduced, his period will necessarily be altered by the new calculations that will be introduced to complete the motions of all the primary planets.

The reader will recollect that when we explained the mode of converting a tropical calculation into a synodic train, we subtracted the denominator of the large ratio, put into the form of a fraction from the numerator; that is, we *ejed* unity from the value, as a compensation for the *addition* made to each revolution by the *mode* in which the wheels are

PLANETARIUM.

placed to act; we have therefore, in reversing the operation to find the value of the train for a tropical period, substituted + for -, and by this substitution have given in their lowest terms the identical numbers that the author calculated to express the ratios of the respective tropical periods, before they were metamorphosed into numbers suitable for synodic trains. If we conceive, when all the planets are in motion, that the first mover is Georgian and the last the handle, which would be the case, if any external force were applied to Georgian's arm instead of to the handle, then the explanation will be obvious of the necessity that exists for *rejecting unity* out of each improper fraction, that is composed of the ratio of any two contiguous periods. Let us suppose Georgian's arm pushed forward by any force in the direction of the planet's proper motion, then, by looking at the figure, we shall see that the lowest wheel 171, which is made fast to the central stem, will produce a motion in the little pinion 20, which is given again to the small wheel 39, by the medium of its attached wheel 28; but wheel 39 cannot revolve without moving its fellow, or wheel 129 made fast to Saturn's arm, therefore Saturn's arm must evidently have a motion from this direct action of the small wheels; but the small wheels in question are supported by and carried round upon Georgian's arm; and if they did not revolve at all, by their connection with Saturn's arm they would make Saturn revolve in the same time with Georgian; or in other words, if pinion 20 were even detached from wheel 171, Saturn's and Georgian's arms would move as one arm, on account of the connection of the small wheel 39 with the large one 129, the former being fast to one arm, and the other to the other. Thus the arm of Georgian in each of its revolutions, *pushes* Saturn's arm *once* round independently of the direct effect of the train, and hence the number of Jupiter's revolutions in one of Georgian was diminished by *one*, when the wheelwork was calculated; which diminution shews the inventor's foresight as well as ingenuity; and hence we must add *one* of those revolutions to the revolutions simply produced by the train, in order to obtain the combined effect of the two separate causes of motion.

In the same way Saturn's arm may be said to push that of Jupiter once round in each of Saturn's revolutions, and so of the rest till we arrive at Mercury, which is pushed by Venus in the manner we have described, when the moving force is applied at Georgian. The same effect takes place when the force is applied at the handle, but on that supposition is not easily explicable by inspection.

From what has now been explained, it will be perceived, that all the arms, or radii vectors of the planets, are so connected together, like so many links of a chain, that no one can move without giving motion to all the rest, and that therefore when once rectified they will be always so for some specified year or other, which may be known from the situation of Georgian's arm, that rests on a roller supported by the large ecliptic plate surrounding the table; and the month will be indicated by the earth's arm, as well as the day by the index at the handle. But these motions of the arms, partly derived from the wheels and partly from the mutual connection of the arms themselves, are *mean motions*, like the motions produced in the common planetarium; and it remains yet to be explained, why the inventor preferred the more complex construction.

In *fig. 2.* Saturn's arm is detached, in order to shew how the equations and variations of distance are effected in all the orbits by the help of the mean motions; this arm, like Jupiter's and Georgian's, is made of wood, and gilt, for the sake of lightness; but an edge-bar of brass is screwed

to it, to give it strength, which is in contact with it the whole length from A to B: immediately above the centre of motion of this arm is a pulley, fixed to the central stem between the arm and the fixed wheel, indeed the pulley is made fast to the under face of the wheel; then another similar pulley is placed on the remote end of the arm, so that an endless gut, embracing both, may give motion to the pulley at B, as the arm revolves round the fixed pulley under the wheel A. Under the pulley, B, is an oblong aperture in the arm, through which the stud passes, on which the pulley revolves, and as this stud is tapped into a screw below, a nut fixes it so that any degree of tension may be given to the gut that may be requisite for moving the pulley, or even for supporting the weight of the arm's appendages. A short arm, B C, is made fast to the pulley B, and revolves with it once in each revolution of Saturn, by reason of the two pulleys being of the same dimensions; but the motion is in a contrary direction to that of the arm; now, we have shewn, under our article *EQUATION Mechanism*, that if the short arm, B C, bear the same proportion to the radius vector, or long arm A B, that the mean distance of the planet does to the excentricity, a point fixed at C will describe an *excentric circle*, very nearly similar to the real orbit of the planet, and all the variations of *distance* will be exhibited as nearly to the truth, as such an orbit is to the true elliptic orbit itself; and in all the orbits of small excentricity, the difference, even on a large scale, is hardly perceptible. But though such a point would always shew the distances properly, it would produce only *one-half* of the acceleration and alternate retardation on mean motion that is due to such excentricity; and doubling the short arm B C, so as to make it give the whole acceleration and retardation, or, which is the same thing, the *whole equation of the centre*, would exhibit improper variations of distance, by giving them in excess by one-half; therefore to fulfil the two conditions of variable velocity, and of variable distance, the short arm B C was made equal to $\frac{2}{3}$ ds of the excentricity, or once and a half, and another short arm, C D, was made to revolve round its extremity *twice*, while the arm B C revolves once, that is, twice in each revolution of the planet; this effect is produced by another couple of pulleys, one just double of the other, the larger one fixed fast over pulley B, and the smaller over the point C, while the stem of the planet rests at the point D, at the remote end of the second small arm; under these circumstances the smallest arm C D, which is just one-third of the length of the other small arm B C, has a direct motion, while that of the other arm is retrograde, and the effect produced by their united motions is a due representation of both the *equation* and *distances* in every part of the orbit. But in order that the little arms might have the proper motions imparted to them, it was necessary that the pulley A should be fixed immovably, which would not have been the case had it been inserted on a revolving tube, and as each arm has a fixed pulley, like that of Saturn, which we have described, as well as a fixed wheel, the system of concentric revolving tubes was evidently incompatible with the demands of this construction. On the axis of pulley B, and under it, close to the long arm, is made fast a silvered circular plate, that contains the equations and latitudes of the planet, and this plate, when fixed in its due situation by the nut under the arm, is pointed to by a hand attached to the pulley, that revolves along with it. Thus, not only is the planet carried in its excentric path, according to the Keplerian law of planetary motion, but its equation and latitude are also indicated, at the same time that the mean motion is referred to the large ecliptic by the long arm of equable motion; so that the exact correspondence between the

PLANETARIUM.

the construction of the planetary tables, and of the motions produced by this machine, affords the best possible illustration of the process by which the places of the planets are calculated for the Nautical Almanac, and the machine may be considered as a species of perpetual self-calculating almanac.

It is true, the planets are made to revolve all in the same plane, which, in an horizontal machine, could not well be avoided, yet the stems of those that deviate any sensible distance from the ecliptic, are composed of tubes that draw out, or push in, to the required marks made on them, by way of graduation for latitude; and therefore, as the silvered plates exhibit the quantum of latitude, north or south, at all times, it is an easy matter to draw out, or to push in, at any time, the planet's stem, till the planet stands at its due latitude, as seen from the sun, on that particular day. The proportional distances, however, of all the planets could not possibly be preferred in the lengths of the arms, and therefore the subjoined proportions were adopted, which we will give in a table that shall contain also the corresponding lengths of the second and third arms.

Lengths of the respective Arms.

Planets.	Radii Vectores.	First short Arms.	Second short Arms.
	Inches.	Inches.	Inches.
Mercury	1.54	0.62	0.0
Venus	2.9	0.0	0.0
Earth	4.0	0.0	0.0
Mars	6.1	1.14	0.0
Vesta	9.4	1.17	0.39
Juno	10.6	4.04	1.34
Ceres	11.06	1.31	0.43
Pallas	11.06	4.15	1.38
Jupiter	20.8	1.50	0.50
Saturn	$\frac{3}{4} = 28.65$	2.48	0.83
Herfchel	$\frac{1}{2} = 38.4$	2.70	0.90

From this table it will be seen that none of the planets have two small arms till we come to Vesta, and the reason is, because their mean distances from the sun are too small to admit of such addition, and also Venus and the Earth have their equations too small to require them. We might also have added a table of dimensions of the wheelwork, if there had been any difficulty in obtaining the due sizes, but as each train may have its wheels of any diameter, provided its large driving wheel be larger than its subjacent fixed one, in order to admit of an intermediate pinion of any number of teeth, the workman may fix on any dimensions that will admit of teeth to be from eight to ten *per* inch, provided those pairs which act together be duly proportioned to each other. In the trains of the Sun, of Mercury, and of Venus, where there is but little stress on the teeth, the wheels may have 14 or 15 teeth *per* inch, without any danger of injury.

In the train of Georgian the driving wheel of 129 has only about seven teeth in the inch. The wheels on the Earth's arm have their diameters limited, the distance from the sun to the Earth being exactly four inches; hence the diameter of each of the wheels of 107 teeth is 2.53 inches, that of 62, 1.47, and that of 86, 2.0, and each of them have 13.4 teeth in every inch of their geometrical circumference. The fatalities are made to move by hand, as in other planetaria, and the dimensions of the ivory balls are optional. What we have said under our article ORRERY, respecting the *rectification* of that machine, will apply to a planetarium also; we will therefore conclude our account of the present planetarium by subjoining such tables as are requisite for graduating the silvered faces that indicate the equations and latitudes of the planets, which tables will be a proper supplement to those of the sun and moon, which are before explained, and with which we concluded our article ORRERY.

TABLE I.—The angular Distances of Mercury from the Aphelion and Perihelion Points, which correspond to exact Degrees of Equation.

PLANETARY, something that relates to the planets.

In this sense we say, planetary worlds, planetary inhabitants, &c. Huygens and Fontenelle bring several probable arguments for the reality of planetary worlds, and animals, plants, men, &c. The former in his *Κοσμοθεωροί*, five de Terris Cœlestibus; the latter in his *Dialogues, sur le Pluralité des Mondes*.

PLANETARY Hours, in *Chronology*. See HOUR.

PLANETARY Days. Among the ancients, the week was shared among the seven planets, each planet having its day. This we learn from Dion Cassius; and Plutarch, *Sympof. lib. iv. q. 7*. Herodotus adds, that they were Egyptians who first discovered what god, that is, what planet, presides over each day; because among this people the planets were directors. And hence it is, that, in most European languages, the days of the week are still denominated from the planets; Sunday, Monday, &c.

PLANETARY Years, the periods of time in which the several planets make their revolutions round the sun, or earth.

As from the proper revolution of the sun, the solar year takes its original; so from the proper revolutions of the rest of the planets about the earth, so many sorts of years do arise, viz. the Saturnian year, the Jovial year, the Martial year. For Venus and Mercury, as their years, when judged of with regard to the earth, are almost equal to the solar year; they are more usually estimated from the sun, the true centre of their motions. See periodic times under PLANETS, *supra*; and YEAR.

PLANETARY Machines, an *Historical Account of*.—"The apparent motions of the heavenly bodies," says professor Vince, "are the most obvious phenomena in nature; and as a knowledge of the return of the seasons must always have been necessary for the husbandman, the course of the sun probably engaged the attention of mankind in the early ages of the world." Accordingly the Jewish historian, Josephus,

PLANETARY MACHINES.

Josephus, tells us, that the sons of Seth applied themselves to the study of astronomy, and engraved their observations on pillars of stone to survive the deluge; and that Abraham read lectures on astronomy to the Egyptians. Berofus, the Chaldean author, also says, that Providence prolonged the life of the antediluvians, on purpose that they might improve in virtue, and in the knowledge of geometry and astronomy, which were deemed essential to human welfare. Indeed, if we search into the history of the Chinese, Brahmins, Chaldeans, or Egyptians, we find that astronomy was cultivated by each of these nations soon after the dispersion of the human race and confusion of tongues. So much it seemed necessary to premise on the antiquity of astronomy itself, before we entered upon a detail of the different machines which have been constructed to represent the different systems which prevailed at the time of their construction; and, indeed, the histories of astronomy, and of astronomical instruments, are so intimately united, that they cannot be separated, but throw mutual light on each other.

To ascertain the date and particulars of the *first* machine which was invented for representing the motions of the heavenly bodies, is the province of the antiquarian, rather than of the cultivator of science; but as the order of *time* seems to be the most systematic to adopt in a regular description of different celestial machinery, it shall be observed, as far as the materials that we have collected will furnish an historical sketch.

The first celestial mechanism of which we have met with any intimation, is the Chinese sphere, mentioned by professor Vince in his excellent Treatise on Astronomy (vol. ii. p. 253.), which was made by Yu-chi, in the reign of the emperor Hoang-ti, in the year before Christ 2697, and which is described as having had many both moveable and fixed circles belonging to it; but with respect to further particulars, we are not in possession of any information.

The next machine that occurs is also a Chinese sphere, mentioned by Martiu, in his History of China, as being made by a man of the name of Xuni, 2400 years before Christ. His words are these; "Xuni, 2400 ans avant J. C. fit faire une sphere d'or, enrichie de pierreries, ou l'on voyoit les sept planetes, et la terre au milieu:" *i. e.* "Xuni, 2400 years before Jesus Christ, had a sphere made of gold, enriched with precious stones, in which were to be seen the seven planets, and the earth in the middle." This short notice informs us what the system of the early Chinese astronomy was, and exactly accords with the account we have of the astronomical system of the Brahmins, who not only supposed the earth to be the centre of the planetary orbits, but also believed that it was placed on a mountain of gold, to which probably the golden sphere had some reference.

A third Chinese sphere is mentioned by Dr. Long in his Astronomy, vol. ii. p. 662, as having been made 2277 years before the Christian era by Chun, who, on succeeding Yao, found a great quantity of gold and jewels, of which he made a sphere that included the seven planets.

The contriver of this machine must have had the advantage of the astronomical determinations of the astronomers Hi and Ho, who about the year before Christ 2332, amongst other astronomical notices, determined that *one* year should consist of 366 days, and *three* of each 365, alternately. It will probably be said, that the emperor might have made a better use of his newly found treasure than in converting it into a sphere, but perhaps he had the circumstance in his recollection, that 2513 years before Christ, or 181 years before that time, Chueni was created emperor

of China entirely on account of having calculated an ephemeris of the motions of five planets.

We do not meet with any mention made of instruments constructed by the Chaldeans or Egyptians for representing their system of astronomy, though they cultivated astronomy very early, nor does it appear quite certain what their system was. According to the authority of Macrobius, the ancient Egyptians made the planets revolve about the earth, and reckoned the sun to be a planet, with Mercury and Venus revolving as secondaries round him; and Diodorus Siculus says, the ancient Egyptians discovered that the planets (superior as well as inferior) had sometimes a direct, and sometimes a retrograde motion, and that they were sometimes stationary. He also asserts, that they made the sun move in a circle inclined to the equator, and in a direction contrary to the diurnal motion. These accounts favour the idea, that systems, somewhat different, were adopted, either at the same time, or successively; but that a system with the earth in the centre was the prevalent one, particularly among the later Egyptians, may be thus inferred. The Alexandrian school, we believe, is universally allowed to have given the names of the planets to the days of the week, which names are yet retained in the Latin language. Philander, in his learned notes to Vitruvius, has given us two reasons for the order Dies Saturni, Solis, Lunæ, Martis, Mercurii, Jovis, Veneris, *viz.* Saturday, Sunday, Monday, Tuesday, &c. This arrangement may have puzzled many of our readers who have considered it, and who probably have not been able to find out the reason of such a succession. The first reason, says Philander, is said, in the seventeenth book of Dion, to be this: "Cum exitimarent Egyptii, planetarum eum esse ordinem, ut orbis summus Saturni diceretur, proximus Jovis, tertius Martis, quartus Solis, quintus Veneris, sextus Mercurii, septimus Lunæ; diatessaron harmoniæ rationem habentes, quod in eâ vis omnis musica contineretur, orbium tetrachorda septem commenti sunt, quorum singulas primas stellas singulis hebdomadis diebus assignarent. Primum tetrachordum a Saturno ad Solem concipiebant, secundum a Sole ad Lunam, tertium a Luna ad Martem, quartum a Marte ad Mercurium, quintum a Mercurio ad Jovem, sextum a Jove ad Venerem. Inde factum, ut primus dies sit appellatus Saturni, quia primi tetrachordi princeps erat Saturnus, et pari ratione secundus Solis, tertius Lunæ, quartus Martis, quintus Mercurii, sextus Jovis, et septimus Veneris:"—that is,—“As the Egyptians thought the order of the planets to be such, that the orbit of Saturn was called the highest, that of Jupiter the next, that of Mars the third, that of the sun the fourth, that of Venus the fifth, that of Mercury the sixth, and that of the moon the seventh; conceiving a certain harmonic ratio to run by *fours*, as the groundwork of music, they made seven tetrachords (as they called them) of the orbits, and assigned the first planet of each (tetrachord or space of *four* successively) to each day of the week. Thus they imagined the first tetrachord to reach from Saturn (the highest) down to the sun, the second from the sun down to the moon, the third from the moon round again to Mars, the fourth from Mars down to Mercury, the fifth from Mercury round a third time to Jupiter, and the sixth from Jupiter down to Venus. Hence it came to pass, that the first day was called Saturday, or day of Saturn; the second Sunday, or day of the sun; the third Monday, or day of the moon; the fourth (or Tuesday) the day of Mars; the fifth (or Wednesday) the day of Mercury; the sixth (or Thursday) the day of Jupiter; and seventh (or Friday) the day of Venus.”

PLANETARY MACHINES.

The other reason of this order of the planetary names of the seven days, as given by Johannes Oxiphelinus, was this: "Cum naturalis dies quatuor et viginti horis constaret, primam dabant Saturno, secundam Jovi, tertiam Marti, quartam Soli, quintam Veneri, sextam Mercurio, septimam Lunæ; rursum octavam Saturno, nonam Jovi, ac deinceps ad vicefimam quartam, quæ Martis cum esset, contingebat, ut proximæ diei prima esset Solis, tertix Lunæ, quartæ Martis, quintæ Mercurii, sextæ Jovis, et septimæ Veneris. Ex eo diebus hebdomadis planetarum inditum est præfidium, quos memorato ratiocinio primis horis præesse contigerat. Quem morem receperunt longo post tempore, & non ita pridem, Græci & Romani. Et revera, ut legas omnia omnium antiquorum monumenta, nunquam reperias eam dierum appellationem."—Namely: "As a natural day consists of 24 hours, they gave the first to Saturn, the second to Jupiter, the third to Mars, the fourth to the Sun, the fifth to Venus, the sixth to Mercury, and the seventh to the Moon; again the eighth to Saturn, the ninth to Jupiter, and so on till the twenty-fourth, which happening to fall to Mars, made the sun the first of the next day, the moon the first of the third day, Mars of the fourth, Mercury of the fifth, Jupiter of the sixth, and Venus of the seventh. Hence those planets to which the first hour of each day fell, by this mode of counting, were made to preside over those particular days: which mode the Greeks and Romans did not adopt till a long time afterwards, indeed not till recently: and in tracing the inscriptions of the ancients this manner of naming the days is not to be met with."

Thus have we two reasons given for the origin of the same custom, of equal authority and probability; both of which may be easily understood if we describe a circle and divide it into seven equal portions, and mark them successively with the characters ♄ ♃ ♂ ♁ ♁ ♁ ♁ ; for the extent from ♄ to ♁ will make the points of a pair of dividers fall successively thus, ♄ ♃ ♂ ♁ ♁ ♁ ♁ , which are in the same order of succession, as the days of the week which they respectively represent; also if, according to the second reason given, we begin with ♄ and count to 24, the first of the next 24 will be ♁ , and of the next 24 ♁ , and so of the rest.

Whichever of these reasons was the original one for thus designating the days of the week, it is equally evident *what* the Egyptian system was at the period this astronomical nomenclature was assigned; the earth was evidently placed in the centre, and the sun was considered as a planet revolving round it in a year; and it is worthy of remark that Saturday, which was the Jewish sabbath, was made the first instead of the seventh day of the Egyptian week.

Perhaps we shall be pardoned the short digression, if we should remark here, that a natural and easy solution presents itself, from a consideration of the Chaldean and Egyptian system of astronomy, of the difficulty of those passages of scripture, which relate to the motion of the sun, and which have been used to countenance the cavils of some of our modern Deists: in Joshua, chap. x. verses 12, 13, it is said that the sun and moon stood still for the space of a whole day; and in the prophet Isaiah, chap. xxxviii. v. 8. it is said, that in order that the shadow might go back on the dial of Ahaz, "the sun turned ten degrees backward, by which degrees it was gone down;" and again in the second book of Kings we read, chap. xx. v. 11. the Lord "brought the shadow ten degrees backward, by which it had gone down in the dial of Ahaz." The objection to these passages has been that they attributed a motion to the sun which is not agreeable to the true solar or Copernican system, as now

unquestionably established; the answer to which, and in our opinion a complete answer, arises out of the system at present before us: which is this, that at the time when these passages were written, the prevailing system was, that the sun actually moved as the fourth or middle planet, once round the earth as its centre, from west to east in a year, and also, in common with all the other planets, moved along with their primum mobile once round from east to west in 24 hours: if, therefore, scripture had said that to produce the effect in question, "the rotation of the earth on its axis was suspended for a day," or that "the earth turned backward on its axis ten degrees," such language would have been *unintelligible* to the people of that remote age, who knew not that the earth was a planet, nor yet that she has a rotation on her axis, to produce the changes of day and night; the expressions, consequently, in this, as in all other instances that we know of, were suited to the *apprehensions* of the people to whom they were addressed, and were on that account sufficiently expressive of the magnitude of the miracles which were performed by divine agency, for purposes of importance sufficient to justify our credence of the facts related.

If it should be here objected, that in one of the passages quoted, it is said that the *shadow* went back *ten degrees*, and that in another of them it is said, the *sun* went back *ten degrees*, whereas in dials in general the degrees on the face do not correspond in each hour, nor indeed in any hour, to the degrees of the sun's apparent motion in the heavens, our further answer is, that in equinoctial dials, which were the earliest, as well as most simple, and the easiest to make, the degrees on the dial-plate do exactly accord in number with the degrees of the ecliptic; until, therefore, it has been shewn, that the dial of Ahaz was not an equinoctial dial, the objection will not apply: on the contrary, there are other reasons besides the above for supposing that it was an equinoctial dial, one of which will suffice to mention, which is this: when Vitruvius is speaking (chap. iv.) of the origin of sun-dials, he says, "Ea autem sunt divina mente comparata, habentque admirationem magnam, considerantibus, quod umbra gnomonis æquinoctialis alia magnitudine est Athenis, alia Alexandria, alia Romæ, non eadem Placentiæ, caterisque orbis terrarum locis."—"These things are comprehended by minds which are as it were divine, and afford much admiration to those who consider them, because the shadow of an *equinoctial gnomon* is different in length at Athens, at Alexandria, at Rome, at Placentia, and at other parts of the world." This extract serves to shew that the equinoctial dial was generally known in Egypt, Greece, Rome, and other parts of the globe before the time of the Romans. It was, indeed, an attentive observation and measurement of the length of the shadow compared with the height of the gnomon of a dial, which led to a knowledge, amongst other things, of the obliquity of the ecliptic with respect to the equator, in very early ages; and it is by comparing more modern observations on the sun's place, when crossing the equator, with ancient determinations effected in this manner, that later astronomers have been enabled to determine not only the annual precession, or rather retrocession of the equinoctial points, but have thereby very nearly ascertained the period in which some of the ancient astronomers flourished, and also the authenticity of many historical facts.

From Egypt, it is generally understood, that Thales of Miletus first introduced a knowledge of the circles of the sphere, and the causes of solar and lunar eclipses into Greece, about six centuries before the Christian era, and that he calculated

PLANETARY MACHINES.

culated an eclipse, probably from the assistance of the *Chaldean Saros*, which was a period of 223 lunations, or 6585½ days for the revolution of the nodes, from which a lunation was determined to be 29^d 12^h 44^m 7ⁿ, which is only about 4" above the period that our best tables are calculated from.

Very soon after this time Anaximander, the scholar of Thales, who died in 547 A.C., taught that the earth was a sphere placed in the centre of the world, and that the moon borrows her light from the sun. Pliny says that he first discovered the obliquity of the ecliptic, but this must be a mistake, as we have before seen, that it was known to the Egyptians, unless, indeed, we discredit the authority of Diodorus Siculus; the invention of the sun-dial has also been attributed to him, but this is equally doubtful: he might probably be the first who made one in Greece.

A short time after Anaximander, Pythagoras of Samos became famous for his knowledge of astronomy, which he gained from the priests in Egypt; it is generally said that he placed the sun in the centre of the system, and laid the foundation of the Copernican system, but Laertius affirms that the system he held was, "that the earth was in the centre, with a diurnal motion, in the next place the moon, then the sun, and then the orbits of the planets." His disciple, however, Philolaus of Crotona, about the year 450 B. C. placed the sun in the centre, with the earth and other planets revolving round him; and soon afterwards Hicetas of Syracuse gave the earth a diurnal motion; and Plutarch says, that Pythagoras in his old age repented that he had not given to the earth its proper place. We might mention other names of men who contributed to the advancement of astronomy, if it did not interfere too much with our plan; but we must not omit to mention here Eudoxus of Cnidos, who was a scholar of Plato, and who, about 360 years B. C., made not only a sun-dial, but also a sphere or globe, with the constellations marked on it, as Chiron the centaur is said by fabulous history to have done before. According to Seneca, it was he who brought the hypothesis of the motions of the five planets out of Egypt into Greece.

About 300 years before Christ, Euclid of Alexandria wrote his admired treatise on geometry, which paved the way for astronomical calculations; and about a century after him the celebrated Grecian mathematician Archimedes, not only wrote a description of the sphere, but actually constructed one, in which, it should seem from the account of the Roman poet Claudian, the sun, moon, and planets had their respective motions, which they were at that time supposed to have in the system of nature, and that the globe which surrounded these moving bodies was made of glass, and had the constellations depicted on its surface: and as Archimedes had invented an engine for raising great weights by wheelwork, there can be no doubt but that wheels and pinions were introduced in his sphere to produce the respective motions. The description alluded to is this; *viz.*

" Jupiter in parvo cum cerneret æthera vitro,
Risit, et ad superos talia dicta dedit:
Hucine mortalis progressa potentia curæ!
Jam meli in fragili luditur orbe labor.
Jura poli, rerumque fidem, leges que Deorum
Ecce Syracusius transtulit arte senex.
Inclusus variis famulatur spiritus astris,
Et vivum certis motibus urget opus.
Percurrit proprium mentitus signifer annum,
Et simulata novo Cynthia mense redit:

Jamque, suum volvens audax industria mundum,
Gaudet, & humanâ sidera mente regit.
Quid falso infontem tonitru Salmoneæ miror?
Emula naturæ parvo reperta manus."
Epig. in Spher. Archimedis.

As the translation which Dr. Derham has annexed to this quotation is not remarkable for its elegance, we beg leave to substitute the following:

" When Jove beheld in glass his heaven made,
He laugh'd, and to the deities thus said:
That human power and art should so succeed
With brittle orb, to imitate my deed!
Behold! that aged Syracusan's skill
Has made the very skies obey his will.
An hidden spirit guides, by certain laws,
Each animated planet as it goes.
The sun, well feign'd, his annual circuit makes;
And Cynthia too her monthly journey takes:
Man now by industry too bold is grown,
With joy who dares to make the world his own.
Why wonder at Salmoneus' dreadful lot?
Since nature's artill has a rival got."

The poet could not better express his admiration of the mechanism in question, than by supposing Jupiter more enraged at the sight of it, than he was at the king of Elis, who imitated his thunder by driving a chariot over a brazen bridge, and by throwing down burning torches at the same time instead of lightning; for which presumption, the story is, that he was hurled headlong by a thunderbolt into the infernal regions: but when we consider that the "hidden spirit" which actuated the various motions was probably a *dead weight*, his incensed majesty had not much reason to be jealous in either instance. Besides the above authentic account of the sphere of Archimedes, we have the two following notices of the Roman orator Cicero; the first is in the Tusculan Questions, where, as an argument to prove the divine nature of the soul (lib. i.) he introduces the contrivance of Archimedes thus: "Nam cum Archimedes lunæ, solis, quinque errantium motus in spheram illigavit, effecit idem, quod ille, qui in Timæo mundum ædificavit Platonis deus, ut tarditate, et celeritate dissimillimos motus una regeret conversio. Quod si in hoc mundo fieri sine deo non potest, ne in spherâ quidem eisdem motus Archimedes sine divino ingenio potuisset imitari." In English thus; "For when Archimedes connected together in his sphere the motions of the moon, sun, and five wandering stars, he effected the same thing which that god did in Timæus, who built Plato's world in such a manner, that one revolution of it produced motions very dissimilar in slowness and quickness. But if this thing cannot be effected in that world without the aid of a god, neither could Archimedes in his sphere imitate similar motions without a divine genius." And again, in his second book "de Natura Deorum," Tully says, when speaking of the philosophers of his age, "Archimedes arbitrantur plus valuisse in imitandis spheræ conversionibus, quam naturam in efficiendis," *i. e.* they imagined that "Archimedes could better imitate the motions of the sphere than nature could keep them in motion." Such was their veneration of that great philosopher and mechanic.

If we pass over sun-dials which were constructed in very early ages, and clepsydræ or water-clocks, (the invention of which has been attributed by Pliny to P. Cornelius Nasica, 150 years before Christ, but by Vitruvius to Ctesibius

PLANETARY MACHINES.

buis about the same time,) we find no machine or instrument representing the motions, or measuring the periods, of any of the heavenly bodies, till nearly eighty years before the Christian era, when Pofidonius made a sphere which seems to have been similar to that of Archimedes. Cicero's description of it, in his second book "de Natura Deorum," is this; "Quod si in Scythiam, aut in Britanniam, spheram aliquis tulerit hanc, quam nuper familiaris noster effecit Pofidonius cujus singulae conversiones idem efficiunt in sole, & in luna, & in quinque stellis errantibus quod efficitur in caelo singulis diebus & noctibus; quis in illâ barbarie dubitet, quin ea sphaera sit perfecta ratione?" In English thus; "If any one should convey into Scythia or into Britain this sphere which our friend Pofidonius lately constructed, the revolutions of which produce the same effect in the sun, moon, and five planets, as they experience in heaven; who is there in the midst of such barbarity, who could doubt that this sphere is perfected by the operation of reason?"

It is the opinion of Ferdinand Berthoud, a French author, who has written many books on the different branches of clock-work, that this sphere, like that of Archimedes, had wheels and pinions, but that it was put in motion by a water-clock, which kept it going day and night; and to rescue our own country from the imputation of *barbarous ignorance* at the age in question, it is grateful to the feelings of an Englishman to be told, by the same author, speaking of clepsydrae, (Histoire de la Mésure du Temps, tome i. p. 20, 21.) that "Cæsar les trouva même en Angleterre, lorsqu'il y porta ses armes. Cet instrument nouveau lui donna lieu d'observer que les nuits de ce climat étoient plus courtes que celles d'Italie." *i. e.* "Cæsar found them, even in England, when he carried his arms thither. That *new* instrument gave him an opportunity of observing that the nights of that climate were shorter than those of Italy." It must have been in summer that this observation was made by Cæsar, otherwise the result would have been just the reverse.

Besides the spheres above named, Dr. Derham says that Cardan mentions another belonging to Sapor, king of Persia, in the middle of which his majesty could sit, and see all the stars rise and set, though it was made of glass; but whether this was the same Sapor who was contemporary with Constantine the Great, is uncertain; nor is it known what wheelwork or planetary motions belonged to it, nor yet what system of astronomy was the groundwork of the calculations, if there were any.

What the system of the Romans was may be collected from their writings, particularly those of Vitruvius and Tully in his dream of Scipio. The former describes it very minutely in these words; (de Architectura, lib. ix. cap. 4.) *viz.* "Signa cum numero xii, partes que duodecim singula possident mundi, versantur que ab oriente ad occidentem continentur, tunc per ea signa contrario cursu Luna, stella Mercurii, Veneris, ipse Sol, item que Martis, et Jovis, et Saturni; ut per graduum ascensionem percurrentes, alius alia circuitionis magnitudine ab occidente ad orientem in mundo pervagantur. * * * Mercurii autem et Veneris stelle, circum solis radios, solem ipsum, uti centrum, itineribus coronantes, regressus retrorsum et retardationes faciunt."

"There are twelve signs, occupying each a twelfth part of a circle of the world, and turning round continually from east to west; then through these signs, in a contrary direction, run the Moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn, moving, as it were, along an ascent

of steps, each in an orbit of a different size from west to east. * * * But Mercury and Venus moving round the rays of the sun, and considering the sun himself as their centre, make retrograde motions, and experience a diminution of velocity."

Tully's account, which is in a more ornamental style, runs thus (M. Tul. Cic. Somnium Sciponis): "Extimus (orbis) qui reliquos omnes complectitur, summus ipse Deus, arcens et continens cæteros; in quo infixi sunt illi, qui voluntur, stellarum cursus sempiterni; cui subiecti sunt septem, qui versantur retrò, contrario motu, atque cœlum, ex quibus unum globum possidet illa, quam in terris Saturniam nominant. Deinde est hominum generi prosperus et salutaris ille fulgor, qui dicitur Jovis: tum rutilus horribilis que terris, quem Martium dicitis: deinde subter medium fere regionem Sol obtinet, dux et princeps, et moderator luminum reliquorum, mens mundi, et temperatio, tantâ magnitudine, ut cuncta sua luce illustret et compleat. Hunc ut comites consequuntur alter Veneris, alter Mercurii cursus; in infimo que orbe luna, radiis solis accensa, convertitur. Infra autem jam nihil est, nisi mortale et caducum, præter animos generi hominum munere deorum datos. Supra lunam sunt aterna omnia. Nam ea, quæ est media et nona, tellus, neque movetur, et infima est, et in eam feruntur omnia suo nutu pondera."

"The outermost (orb) which furrounds all the rest, is the great God, impelling and holding together all the rest; within which (orb) the eternal courses of the stars, which roll along, are fixed; under this are seven others carried backwards by a motion, contrary to that of heaven, one of which has a globe, called on earth Saturnia. Next is that luminary which is propitious and salutary to man, called Jupiter: then that ruddy and horrible one, which is denominated from Mars; after that, and nearly in the middle region, is the sun, the prince and guide, as well as ruler of all the other luminaries, the mind and regulating power of the world, of such magnitude as to illuminate and fill all places. The courses (or orbits) of Venus and Mercury follow him as his companions; and the moon, lighted by the rays of the sun, is carried round in the lowest orb. Below her is nothing but what is mortal and frail, except the minds of men, which are the gift of the gods. Above the moon all things are eternal. For this Earth, which is the middle (or centre), and the ninth in order, does not move, and is the lowest; and towards it are voluntarily carried all ponderable bodies."

We could produce further accounts of this system from Pliny, Martianus Capella, and Cassiodorus, if more were deemed necessary for our purpose; but we have perhaps already dwelt too long upon the accounts of heathen authors to be consistent with our plan, of giving only a history of planetary machines; we will therefore subjoin only one further remark with respect to these authors and their system, which is, that many of our words, particularly epithets, are evidently taken from this order of the planets, and owe their original signification to it; such are the words *supernal*, *infernal*, *superior*, *inferior*, *sublunary*, *solstice*, *sun's path*, *ascension*, *descent*, *declination*, and others which we still retain, notwithstanding we have placed the sun in the centre, and made the earth a planet to describe the same orbit which was formerly attributed to him.

It being then probable, that, as the ancient Egyptian was the prevailing system on the continent before and for some time after the Christian era, the machines which were invented before and about that memorable period, were contrived to exhibit *diurnal*, as well as contrary *annual* revolutions

PLANETARY MACHINES.

tions of all the planets, except of Mercury and Venus, which planets were made to revolve as secondaries to the sun, or second planet in order from the centre; the moon being the first: such a system would exhibit the phenomena relating to the sun, Mercury, Venus, and moon very well, but would not give a representation of the retrogradations of our superior planets.

Ptolemy, who died about 138 years after the commencement of the Christian reckoning, saw the difficulty of explaining the retrogradations of the superior planets by the Alexandrian system, and therefore devised the circles and epicycles that distinguish his system, in order to account for the apparent irregularities of the planetary motions; and though he probably could not construct a machine to represent the said motions exactly, yet in his *Almagest* is described a sphere, with the constellations depicted thereon, to which he could refer the apparent paths of the heavenly bodies, and by which he could explain his system.

From the time of Ptolemy to the sixteenth century, in which Copernicus revived the system of Philolaus, or as is generally said of Pythagoras, the machines which were constructed we must suppose represented the Ptolemaic system, which, like the Egyptian, placed the earth in the centre, but supposed the moon and planets all separately revolving round it every day, whilst they slowly performed periodic cycles and epicycles, to account for the stationary and retrograde appearances, that could not otherwise be explained. The most ancient machine of which we have met with any account during this period is that of Chromatius, the governor of Rome, in the third century, which is mentioned in the first volume of Beckmann's "History of Inventions and Discoveries." According to the accounts of St. Sebastian and St. Polycarp, this costly piece of mechanism consisted of a pavilion of glass, in the construction of which were consumed two hundred pounds weight of gold, as materials for the workmanship; and all the heavenly bodies were represented by mechanism, together with the change of the phases of the moon: there appears to have been also an ecliptic circle divided into signs. But whatever the particular construction of this machine may have been, it was lost to posterity by the violent hands which the saints laid upon it, either on account of the valuable materials of which it was constructed, or by reason of some supposed impiety attached to such a representation of the heavens. St. Sebastian represents Chromatius as speaking thus; "Habeo cubiculum holovitreum, in quo omnis disciplina stellarum ac mathesis mechanicæ est arte constructa in cujus fabricâ pater meus Tarquinius amplius quam ducenta pondo auri dignoscitur expendisse," *i. e.* "I have a chamber of glass, in which all the knowledge relating to the stars is laid down by mechanical contrivance, in the construction of which my father Tarquin is known to have consumed more than two hundred pounds weight of gold:" to which St. Sebastian answers, "Si hoc tu integrum habere voveris te ipsum frangis," *i. e.* "if you wish to preserve this entire, you ruin yourself;" to which Chromatius replies, "Quid enim? mathesis aut ephemeris aliquo sacrificiorum usu coluntur, cum tantum eis mensium et annorum cursus certo numero per horarum spatia distinguuntur? Et lunaris globi plenitudo, vel diminutio, digitorum motu, rationis magisterio, et calculi computatione preveditur?" (*Act. Sanc. Seb. cap. 16.*) *i. e.* "But why? this knowledge of the daily motions, is it not useful for the observance of the sacred rites, seeing that the lapse of months and of years is distinguished by the passage of a certain number of hours? And are not the increase and decrease of the lunar globe foreseen by the motion of indexes, guided according to certain calcula-

tions?" St. Polycarp, speaking of the same mechanism, uses these words; "Illic signa Leonis, et Capricorni, et Sagittarii, et Scorpionis, et Tauri sunt; illic in Ariete Luna, in Cancro hora, in Jove stella, in Mercurio tropica, in Venerè Mars, et in omnibus istis monstruosis dæmonibus ars deo inimica cognoscitur:" that is, "There are the signs of Leo and of Capricorn, of Sagittarius and of Scorpion, and of Taurus; there are the moon in Aries, the hour-hand in Cancer, a star in Jupiter, the tropic in Mercury, in (or with) Venus Mars; and in all those monstrous dæmons is discovered an art hostile to the Deity."

The next instrument in the order of time which occurs in our research, is that which was contrived by Y-tang, the celebrated Chinese astronomer, in the year 721, and which merited the admiration of his contemporaries. Berthoud (tome i. p. 38, and tome ii. p. 178, 179, *Histoire de la Mésure*,) speaks of this instrument in the words of father Gaubil, thus: "L'eau faisoit mouvoir plusieurs roues; et par leur moyen, ou representoit le mouvement propre, et le mouvement commun du soleil, de la lune, et des cinque planetes; les conjonctions, les oppositions, les éclipses du soleil et de la lune; les occultations des étoiles et des autres planetes."—Which account in English may be thus; "Many wheels were put in motion by water, and by their means were represented both the proper and common motions of the sun, moon, and five planets; the conjunctions and oppositions, the eclipses of the sun and moon, and occultations of the stars, as well as of the planets."—By the proper and common motions, we conceive, we must understand the apparent or supposed diurnal motion of the planets round the earth, as well as their progressive motions in the ecliptic, and also the lunation and motion of the moon's nodes. For it is said, moreover, that this instrument exhibited, by two pointers, the hours of the day and night, and also the *ke*, or hundredth part of the Chinese day; and it may be worthy of remark here, that at every return of the index to the *ke* a little wooden statue stepped forth, and gave a blow on a wooden board, and then retired; which probably was the origin of *striking* clocks; but what was the regulator of this early horological, as well as astronomical machine, does not appear.

We must now pass on to the eleventh century, in which William, the learned abbot of Hirscham, is said "to have invented a natural horologe in imitation of the celestial hemisphere;" (*naturale horologium ad exemplum cælestis hæmisperii excogitasse*;) but this short notice conveys no exact idea of the construction of this piece of mechanism.

The next machine that we find described is an *horologium*, which, Trithemius says, was presented to the emperor Frederic II., of Germany, by one of the sultans of Egypt, in the year 1232: his description is as follows. "Saladinus Egyptianorum Frederico Imperatori dono misit per suos oratores tentorium pretiosum, mirabili arte compositum, cujus pretii æstimatio quinque ducatorum millium procul valorum excessit. Nam ad similitudinem sphærarum cælestium intrinsicus videbatur constructum, in quo imagines solis, lunæ, ac reliquorum planetarum artificiosissimè compositæ movebantur ponderibus et rotis incitatæ; ita videlicet, quod, cursum suum artis ac debitis spatiis peragentes, horas tam noctis quam dici infallibili demonstratione designabant; imagines quoque xii signorum zodiaci certis distinctionibus suis motæ cum firmamento cursum in se planetarum continebant."—"The sultan of Egypt presented to the emperor Frederic, by his orators, a valuable tent (or pavilion), constructed with admirable art, the value of which has been estimated at more than five thousand ducats. For its appearance within represented the celestial spheres, in which were the representatives

PLANETARY MACHINES.

representatives of the sun, moon, and the rest of the planets, most ingeniously made and actuated by means of wheels and weights; so that, performing their courses in certain stated periods, they designated the hours both of night and day with infallible clearness; the shapes also of the twelve signs of the zodiac distinctly moving along with the firmament, contained upon them the paths of the planets." Here it may be observed the sun and moon are reckoned among the primary planets, according to the Ptolemaic system: and if this horologium was an astronomical clock going by wheelwork, by the power of an appended weight, we think it may be considered as the first of which we have had any description handed down to us: we are at a loss, however, to know what was the *regulator*, if it had any; and also whether the *time* indicated was really *contemporary* with the earth's motion on its axis, (their supposed diurnal motion of the sun,) or only a nominal or *relative* time, many days of which might pass in a short period, when the machine was in quick uncontrolled motion.

Next in order comes an astronomical machine or clock, made by Richard of Walingford, abbot of St. Alban's, in the fourteenth century, which was called Albion (all by one). Leland speaks of the inventor and instrument thus: *viz.* "Electus in monasterii presidem — cum jam per amplas licebat fortunas, voluit illustri aliquo opere non modo ingenii, verum etiam eruditionis ac artis excellentis miraculum ostendere. Ergo talem horologii fabricam magno labore, majore sumptu, arte vero maxima compegit, qualem non habet tota, meâ opinione, Europa secundam; sine quis cursum solis ac lunæ, seu fixa sidera notet, sine iterum maris incrementa et decremента, seu lineas una cum figuris ac demonstrationibus ad infinitum pene variis consideret."—"After being elected abbot, now that his fortune would permit, he wished to give proof, by some illustrious work, not only of his ingenuity, but of his learning also, and skill in the arts: he therefore constructed by great labour, and still greater expence, with uncommon skill, such a machine as, in my opinion, cannot be equalled in all Europe, whether you regard the course of the sun and moon and fixed stars, or you take into consideration the ebbing and flowing of the sea, and the almost infinite variety of lines and geometrical demonstrations." Nearly about the same time John, son of James Dondi, afterwards called Horologius, made a machine similar to the foregoing, which is thus described by Petrus Paulus Vergerius. "In quo erat firmamentum & omnium planetarum spheræ, ut sic siderum omnium motus, veluti in cælo, comprehendantur; festa edicta in dies monstrat, plurima que alia oculis stupenda; tantaque fuit ejus horologii admiranda congeries, ut usque modo post ejus relictam lucem corrigere, & pondera convenientia assignare sciverit astrologus nemo. Verum de Franciâ nuper astrologus & fabricator magnus, fama horologii tanti ductus, Papiam venit, plurimis que diebus in rotas congregandas elaboravit; tandem que actum est, ut in unum, eo quo decebat ordine, composuerit, motum que ut decet dederit:" that is to say, this is a machine, "in which the firmament and spheres of all the planets, together with the motions of all the stars, are contained exactly as in heaven; it points out the festivals and other wonderful things; and so great and admirable was the structure of this horologe, that after his (Dondi's) death, no astrologer could rectify, or assign the proper weights to the different parts. At length, however, an astrologer and famous mechanic of France, attracted by the report respecting such an horologe, came to Pavia, and after many days labour collected the wheels, and put them into such order, as to produce the requisite motions."

The next instrument which we meet with is the famous

astronomical clock at Strasburg, made in 1370, an account of which is given by Conradus Dasypodius in a German book, (Jac von Konigshovens *Elfas* and *Straßb.-Chronik*, p. 574.) which we have not at present before us.

Again, John Werner of Nuremberg, that eminent astronomer and geometer, who first proposed the lunar method of discovering the longitude, about the year 1500 employed Andrew Heirlin, an excellent mechanic, to construct a machine which represented by wheelwork the Ptolemaic system (Doppelmayr de *Mathemat. Nurem.*); but we are not in possession of a more particular account of this machine.

Hitherto we have been able to collect only an historical sketch of astronomical mechanism, as it is connected with the progress of astronomy, without knowing the precise disposition of the parts, or the numbers into which the wheels were divided which produced the various motions; but imperfect as it is, it will furnish us with a proof, that in all ages of the world, a representation of the system of the universe by mechanism has not only been deemed worthy of the efforts of the greatest geniuses, but has been considered as the most arduous and wonderful undertaking.

In coming down nearer to our own time, we propose to admit into our account notices of those machines only, of which we can describe some or all of the powers and properties from authentic sources of information, and concerning which, therefore, we may be able to make appropriate remarks.

The first machines of modern construction that offer themselves to our notice, are the planetary clocks of the late Mr. Peckitt, of Compton-street, London, and the turret clock at Hampton-Court, in both of which are solar and lunar trains of wheelwork; but we have already described those under our article *CLOCK*, and the latter at considerable length; to which we therefore refer our readers for further information.

Next in order after these we may place the famous planetary clock invented by Oronce Finée, mathematician to the kings Francis I. and Henry II. of France, begun in 1553, and made, during the space of seven years, by the best workmen that could be found: this machine was presented to the cardinal du Lorraine, and is at present placed in the library "de Sainte Geneviève," or Pantheon at Paris. The exterior shape of this machine is represented as a pentagonal column, seventeen inches diameter and six feet high, surmounted by a brass celestial globe of seven inches diameter, which contains 48 constellations, and which revolves once in every 24 hours from east to west. The interior part of this pillar contains upwards of one hundred wheels to give the respective motions to the sun, moon, and planets, which are actuated by clockwork, and the whole are kept in their respective motions by one weight suspended within the pillar, the fall of which is one foot *per* day, and the motions continue 48 hours and upwards. The movement of each planet consists of twelve, ten, or eight wheels, as the necessary accuracy requires, and they are all made of Spanish steel and actuated by one common arbor. The description of this elaborate instrument is contained in a printed *recueil*,

N^o $\frac{V}{68}$, of the library at the Pantheon, Paris, in which it is said,

that the increase and decrease of velocity is somehow effected by the mechanism in the motion of the heavenly bodies, which are represented, together with the eccentricities and motions of the apogees, nodes, and latitudes of each. The five plain sides of the pentagonal column have each a brass face of two feet in length, and ten inches in breadth, in each of which are two circles, the upper and the lower, except in that

PLANETARY MACHINES.

that containing the places of the sun and moon, which has three circles; and hands or pointers are made to indicate the different motions on the respective d'or moulu dials or circles, which are appropriated according to the subjoined arrangement, *viz.*

Faces.—1. The motion of Saturn above, and of Jupiter below.

2. The motion of Mars above, and of Mercury below.

3. The motion of Venus above, and of the sun below.

4. The motion of the moon above, and of the moon's node below.

5. The hours above, an astrolabe below, and in the middle the conjunctions, oppositions, eclipses, &c. of the sun and moon.

The wheelwork and other mechanical parts of the instrument are not contained in Berthoud's extract, whence this detail is abridged; but the times of the various revolutions attributed to the movements, and also to the celestial bodies themselves, which are said to be represented to a minute in a revolution, are given in the subjoined table.

Planets.	Whole Periods.				Motion in 24h.
	D.	H.	M.	S.	
Mercury -	87	23	15	36	0 59 8
Venus - -	224	17	53	2	0 59 8
Sun - -	365	5	48	15	0 59 8
Mars - -	686	23	31	56	0 31 26
Jupiter -	4332	14	49	31	0 4 59
Saturn -	10759	4	58	25	0 2 1
Moon -	27	13	18	35	13 3 54
Ditto synodic	29	12	44	3	13 8 35
Ditto nodes -	19 years				

This machine does not exhibit to the eye the representatives of the planets in their orders and distances, but only indicates on the different faces the periods of their sidereal revolutions; the earth is considered by the inventor as the centre of the orbits of the Moon, Sun, Mars, Jupiter, and Saturn, the three last of which are made to move in the Ptolemaic epicycles; but the planet Sol, or sun, is made the centre of the orbits of Mercury and Venus, according to the Egyptian system, which is the reason why the daily progress in the ecliptic is put down for these three alike. It is somewhat remarkable, that this arrangement is not according to the Copernican system, though Copernicus had published his book called the "Revolutions of the celestial Orbs," which laid the foundation of his system, twelve years before; hence we must suppose, either that the book had not found its way from Prussia into France at that time, or else that the system at first met with opposition. Thus an union of the Ptolemaic with the old Egyptian system became the favourite of the astronomer before us, and three years afterwards he published a book in defence of this theory. This machine, then, still in existence, is a standing proof of what has been asserted of the nature of the old original system described by Vitruvius and Cicero, so far

as relates to the inferior planets; and it is highly worthy of remark, that the sidereal periods of our superior planets are nearer the periods according to La Lande, than Dr. Halley gives them, who wrote more than a century after him, and whose astronomical tables were long held in the highest estimation. That the period of Mercury and Venus should not be so accurate, we need not be surpris'd, when we consider that they are made secondaries to the sun; nor can we wonder that there is no distinction made between a tropical and a sidereal year; but we think it certainly surpris'ing, that both the anomalistic and synodic revolutions of the moon are agreeable to the present state of our knowledge of the lunar motions as nearly as may be. As telescopes were not invented at the period we are now treating of, the secondary planets of Jupiter and Saturn were out of the question; but it appears evident from the mechanism before us, that the *mean motions* of those primary planets, which were known two centuries and a half ago, were then determined with that degree of accuracy, which left more modern astronomers little more to do in practical observations, with respect to them, than to contrast their present places with ancient determinations, and so to correct the inaccuracies which have necessarily arisen from want of good instruments of observation.

Planetarium of P. Schirleus de Rheita.—The next machine we meet with is the planetarium of P. Schirleus de Rheita, described in the "Technica Curiosa" of Schott, and made about the year 1650. This machine is said to have represented all the true and mean motions of the planets, their stations, and direct and retrograde appearances, without epicycles or equations, and with very few wheels by the help of endless screws and pulleys. The movements were actuated by water, and on the exterior part of the instrument were three separate faces, or dials, described into a number of circles for the orbits of the planets and signs of the zodiac; the lowest face contained the circles of the Sun, Venus, and Mercury, which were denominated the inferior planets, and their respective hands or arms; the uppermost face had the circles of Saturn, Jupiter, and Mars, with their respective hands; and the face in the middle had twelve hours, and also a circle for the moon. The first wheel which gave motion to all the rest was carried round by a fall of water once in a minute, on the arbor of which was a single endless screw, which drove a wheel of 15 teeth round in as many minutes; on the arbor of this was another similar screw, actuating another wheel of 24 once round in six hours; again, on the arbor of the wheel of 24 was another screw, making a wheel of 20 teeth revolve in five days; and lastly, a screw on the arbor of the last mentioned wheel of 20 impelled a wheel of 73 once round in exactly 365 days, which represented the annual motion of the sun in his supposed orbit round the earth. The last screw also drove a wheel of 45 teeth round in 225 days, which, by the help of two equal pulleys, carried Venus round the sun in this period; and in like manner, it is said, motions were produced in the rest of the planets, but the numbers of the other wheels are not given by Berthoud, from whom this account is taken. Alexander, in his "Traité des Horloges," has anticipated, in some measure, the observations which we should have made in these words; "this machine," says he, "cannot be of great utility, nor will it represent the motions of the planets with sufficient justice; for

"1. The first wheel which moves all the rest, is carried round by a fall of water, which cannot have the requisite regularity.

"2. The movement is not regulated by a balance, pendulum, or fly.

"3. The

PLANETARY MACHINES.

“3. The motion of the sun completes the year in exactly 365 days, which makes an error of 25 days in a century.

4. The discs of the planets are made much too large in proportion to the sun.”

The last of these observations must necessarily constitute an objection in every instrument, where the ball for the sun is not made inconveniently bulky.

We are disposed to think, that the irregularities of motion were not represented by the wheelwork in this machine, which appears not to have had accurate movements, but were indicated by the manner in which the circles were divided, some of which were most likely excentric. The supposed apogee points (not aphelion points) of the orbits of the planets, are put down in the account for the year 1642, thus:

Saturn	26°	53'	of Sagittarius
Jupiter	7	26	of Libra
Mars	29	49	of Leo
Venus	2	12	of Cancer
Mercury	14	6	of Sagittarius
Sun	6	29	of Cancer.

If we add to these numbers the annual motions of the aphelion points, as at present ascertained, the above quoted places will be found to differ only in the *minutes*, except in the instances of Mercury and Venus, in the former of which there is an error of about 2^o₃, and in the latter, if we reckon forwards, of more than seven signs.

The system which is represented by this mechanism is the same as was represented by the preceding one of Oronce Finée, which proves that the Copernican system had not generally prevailed in the middle of the seventeenth century.

It may not be improper to mention here, that Cardan, who wrote in the middle of the sixteenth century, mentions the names of William of Zealand, and Junellus Turrianus, who invented machines of this description about the same time.

Automaton of C. Huygens.—We come now to the first machine, in all probability, which represented the true solar or Copernican system, namely, the automaton planetarium of Christian Huygens; the description of this instrument was not, indeed, published till the year 1703, among the

author's other posthumous works; but Benjamin Martin says, that this was the *original* from which all the more recent instruments were afterwards made, and informs us, moreover, that during the residence of this very ingenious mechanic and able mathematician at Paris, from 1665 to 1681, “he invented and perfected several useful instruments and machines” (Biograph. Phil. p. 340.): we must, therefore, fix the date of the automaton to be in this interval. The learned inventor says, that he had seen and read of many elaborate instruments contrived for exhibiting the celestial motions, but as they were all very imperfect, he employed his mathematical attainments and mechanical skill, for both which he was justly renowned, in constructing a more perfect machine than any which had been before made, inasmuch as it was to represent the excentricities and unequal motions of a system, which was likely to maintain its ground amidst the scrutiny of after ages.

In the “*Descriptio Automati Planetarii*” we meet with an account of the numbers, and a drawing of the wheelwork of this machine, which we briefly shall describe, and attach the proper value to each movement, and then make such observations on them as may occur.

In this machine there is a large watch or clock movement, regulated by a balance and balance spring, which actuates all the planetary motions, and keeps them contemporary with the real motions in the heavens. The motions are thus effected; a pinion of 4, which revolves by means of the clockwork in 4 days, drives a wheel of 45, on the arbor of which is another pinion of 9, driving a second

wheel of 73 once round in a year; $\frac{45}{4} \times \frac{73}{9}$ of 4 days

being equal to 365 exactly. The last mover of 73 has a long arbor lying horizontally, or nearly so, across the machine, on which arbor all the first moving or driving wheels are placed of the different planetary movements; the ratios, therefore, constituted by the wheelwork are so many fractions of 365 days, according to the subjoined plan, in which the value of each separate movement is given in days, hours, minutes, and seconds, respectively: *viz.*

				D.	H.	M.	S.
Mercury's movement	-	-	$\frac{12}{121} \times \frac{17}{7}$	of 365 =	87	21	50 47.4
Venus' ditto	-	-	$\frac{32}{52}$	of do. =	224	14	46 9.2
Earth's ditto	-	-	$\frac{60}{60}$	of do. =	365	0	0 0
Mars' ditto	-	-	$\frac{158}{84}$	of do. =	686	13	8 34.2
Jupiter's ditto	-	-	$\frac{166}{14}$	of do. =	4327	20	34 17.1
Saturn's ditto	-	-	$\frac{206}{7}$	of do. =	10755	17	8 34.2
Moon's lunation ditto	-	-	$\frac{12}{137} \times \frac{12}{13}$	of do. =	29	12	16 34.49

Besides the above wheels and pinions, there is a single screw driving a wheel of 300 teeth once round in 300 years of 365 days each, to show for what year the instrument is at any time rectified: also the wheel of 73 drives a large wheel of 219 teeth round in three years, on which the days and months are marked.

Upon comparing these periods with the exact periods which the best tables give, the reader will observe many very considerable errors, and be disposed to conclude unfavourably of the calculations here employed; but what will be his surprize when he is told that Huygens wrote expressly upon an excellent method of approximating to the

PLANETARY MACHINES.

the truth, in calculations of this kind, which no doubt he employed before he began making his instrument! He will naturally conclude that the scientific contriver of this mechanism has not made the most of his calculations and ingenuity; and that this was really the case may be unquestionably proved; for the fact is, he has calculated periods in fractions of a solar year, and afterwards has introduced a first mover to revolve in a civil year of 365 days, as we have seen; whereas, he ought to have made the annual arbor revolve in 365.242 days, as his calculations supposed, and then the periods would have been these: *viz.*

		D. H. M. S.
Mercury	$\frac{12}{121} \times \frac{17}{7}$ of 365.242 =	87 23 14 47.9
Venus	$\frac{32}{52}$ of ditto =	224 18 20 48
Earth	$\frac{60}{60}$ of ditto =	365 5 48 48
Mars	$\frac{158}{84}$ of ditto =	687 0 4 38.8
Jupiter	$\frac{166}{14}$ of ditto =	4330 17 30 3
Saturn	$\frac{206}{7}$ of ditto =	10748 13 21 49.6
Moon	$\frac{12}{137} \times \frac{12}{13}$ of ditto =	29 12 44 46.35

These periods, being very near the true tropical periods,

must evidently have been calculated from a solar year, and therefore ought to have been produced by wheels placed on a common arbor revolving exactly in that time; hence, the substitution of a proper annual movement in this machine will restore to all the other wheels their proper intended motions, and make the periods what the wheelwork was calculated to effect. See NUMBERS, *Planetary*.

The last moving wheels, which are here put as numerators of the different respective fractions, were so many flat rings with the teeth cut in their posterior or concealed surfaces, and projecting more or less from their planes to meet their drivers; these were supported by intermediate fixed rings with friction rollers at both the inner and outer edges, and the driving wheels or pinions on the common horizontal arbor met their teeth, and impelled them round, whilst they were kept in their proper position by the rollers. On these moveable rings the planetary balls were supported, and the aphelion and perihelion points, latitudes, and shape of the orbits, were marked on the intermediate fixed rings, which, together with the revolving rings, resting on shoulders turned at the outward and inward edges of the fixed ones, formed the cover of the machine, and concealed the wheelwork from sight. The frame was two feet in diameter, and six inches deep, placed in an erect position; and the periods to be represented were collected from the tables of Ricciolus, according to which the solar year was 365^d 5^h 49^m 15^s, and a lunation 29^d 12^h 44^m 3^s, as we now generally reckon it. The aphelia, ascending nodes, inclinations of the orbits, mean distances, eccentricities, and proportional diameters, with respect to the sun, were taken from that ancient astronomer for January 1, 1682, as expressed in the annexed table:

	Aphelia.			Ascending Node.			Inclination.			Mean Dist.	Eccentr.	Diam. comp. with the Sun.
	°	'	"	°	'	"	°	'	"			
☿	15	11	19 ♄	14	29	47 ♄	6	54	0	38806	8149	1 : 308
♀	2	59	44 ♃	13	54	52 ♀	3	22	0	72400	500	1 : 84
♁	7	7	20 ♄							100000	1800	1 : 110
♂	0	30	17 ♃	17	38	12 ♄	1	50	30	152350	14115	1 : 166
♃	7	55	43 ♃	5	30	42 ♃	1	19	20	519650	20558	2 : 11
♄	27	39	46 ♄	21	36	26 ♃	2	32	0	951000	54207	Ring 11 : 37 Do. to ♃ 9 : 4

It should seem from these dates that the instrument was finished in the year 1681, which was the year in which Huygens finally left Paris.

In the machine before us no diurnal motion of the earth, nor motion of the moon's nodes or apogee, was introduced, nor yet the motions of Jupiter's or Saturn's satellites, so that it was properly what is now called a planetarium, and differed from a common planetarium in what it professed to exhibit only, inasmuch as the variable distances and velocities of the planets were attempted to be exhibited: these two requisites are described as being produced in some of the planetary motions by unequal teeth cut in the last moving wheels, and in others by means of rings, cut into equal teeth, and placed excentrically as they regarded the sun: but it has been shewn, when we treated of the different methods that have been devised for producing unequal motion, under our article EQUATION *Mechanism*, that neither of these two methods, adopted by Huygens in his automaton, as he has described them, will produce more than *one half* of the grand equation, and it does not appear that he, in any instance, used them *jointly*; whence we may fairly conclude, that the accelerations and retard-

ations of velocity, being represented in only *half* their due quantity, were much less perfect than the author himself imagined.

Should our readers wish to attain a more clear conception of the internal structure and external appearance of the automaton of Huygens, he may consult the description of Antide Janvier, given in his quarto pamphlet entitled "Des Révolutions des Corps Célestes par le Mécanisme des rouages," (Paris 1812,) who, like ourselves, has given the substance of the original, together with two plates that illustrate the construction, but which did not fall into our hands till our description was finished. From a view of these plates it is evident, that both Mr. Walker's eidouranion, and Mr. Lloyd's celestial mechanism, are copied from the automaton on an enlarged scale, with but little deviation as to the mode of imparting and modifying the respective motions, though we have reason to believe that the periods produced in the latter machines are not so accurate as in the prototype.

Lastly, the objection which father Alexander made very properly to the preceding machine of Schirleus de Rheita, in regard to its losing 25 days in a century, is equally ap-

PLANETARY MACHINES.

plicable to the automaton, exclusively of its other defects; but this objection would be completely obviated by the substitution of an accurate annual movement, which has been just recommended to rectify the other movements.

Romer's Satellite Instrument.—The satellite instrument of Romer, or Roemer, presents itself next to our consideration, an account of which was presented by him to the first astronomer royal, Mr. Flamsteed, in the year 1679. Romer was mathematician to the French king (Louis XIV.) during the period that Huygens was resident at Paris, under royal patronage, and as this instrument was produced during the residence of Huygens, who had a great propensity for mechanics, as well as astronomy and mathematics, we think it extremely probable that Romer's taste for astronomical mechanism was owing to his acquaintance with Huygens; nor is it improbable that the plan and calculations of it might be submitted to the consideration of the Dutch resident.

This is the first machine in which we meet with a number of tubes, or what the French artists have called canons, introduced to move within one another for the purpose of connecting the arms of the planets, or secondaries, with their corresponding wheels, whilst the latter are concealed from sight: this original contrivance was, no doubt, meant to supersede the use of revolving rings and friction-wheels, which were heavy, as well as tedious to make; but then the idea of *variable distances* and *velocities* was given up with its introduction: since the author's time the common planetaria have been made upon this plan, but chiefly with the numbers ascertained by Huygens. (See PLANETARIUM.) The machine before us had a common arbor revolving in seven days, on which all the four driving wheels for the four satellites of Jupiter were fixed fast, which drove each its fellow, placed at the lower extremity of the corresponding tubes; the first satellite had the longest and innermost tube, the second the next, and so on as in the common planetarium.

The numbers of the wheelwork, and their corresponding values in time, may be expressed thus: *viz.*

Wheels.		D.	H.	M.	S.
Sat. 1.	$\frac{22}{87}$ of 7 days =	1	18	28	57.93
2.	$\frac{32}{63}$ of ditto =	3	13	20	0
3.	$\frac{43}{42}$ of ditto =	7	4	0	0
4.	$\frac{67}{28}$ of ditto =	16	18	0	0

There appears to be two reasons why seven days was the period assumed for a revolution of the common arbor; first, because a hand placed upon it would indicate the seven days of the week; and, secondly, because a period of seven days is nearly a mean period between the two extreme synodic revolutions of the 1st and 4th satellites, so that it is not necessary to use either a large wheel or a small pinion.

The four pairs of wheels were intended to be kept going by clockwork, but it does not appear that there was any movement proposed to require an annual index to point out the phenomena beyond the present or current moment, on which account the utility of the instrument was circumscribed.

The periodic errors in this instrument are as follow: *viz.*

In the movement of the 1st	= + 0' 21".93
----- 2d	= + 2 6
----- 3d	= + 0 4
----- 4th	= - 5 7

Romer's Planetarium.—But the satellite instrument of Romer was not the only instrument of which he superintended the construction: in the "*Basis Astronomiæ Roemerii*," Haunizæ, 1735, there is an account of a planetarium by this gentleman, constructed with tubes moving round one another, after the plan of his satellite instrument, and finished in the year 1697. The numbers of the wheels were, according to the size of the machine, as under; *viz.*

		D.	H.	M.	S.	
{	Mercury - $\frac{33}{137}$	-	87	23	28	19
	or ditto - $\frac{13}{54}$	-	88	2	44	30
	Venus - $\frac{24}{39}$	-	224	18	20	48

	or ditto - $\frac{147}{5}$	-	10738	2	54	43

These were the effective wheels of the machine under our present notice; besides which, there were some others of high numbers, which might be considered as dial-work, a part of which effected the revolution of a hand or index in seven days for the week hand, and the rest produced a revolution in ten years, to indicate the year for which the instrument was at any time rectified.

The reason why the author has given the instrument-maker the choice of two pairs of wheels for Mercury, Mars, and Saturn, is, probably, that he might adopt those which best accord with the scale upon which his instrument is to be made. We have here calculated the tropical periods from the standard of an exact solar year; and on examining the numbers, the reader will find that Romer borrowed all his ratios, except those of Mercury, from Huygens; indeed all the modern planetaria of the shops have their numbers taken from the same source, except that, in some instances, 148 has been used for 147 in the wheels of Saturn, either by mistake, or because it was much more convenient to cut into teeth; but the difference occasioned by an omission of this one tooth in each revolution is 127 days' motion; and yet it does not appear that an error of such magnitude has been before detected!

For an account of the manner in which the wheelwork of this planetarium is constructed, and of the mode by which the motion of the planetary bodies are produced, our readers are desired to revert to the title *Common Planetarium*, in our article PLANETARIUM.

PLANETARY MACHINES.

Martinot's Armillary Sphere.—In the "Traité des Horloges" of father Alexander (p. 323.), is contained a description of an instrument made by Martinot, a Frenchman, and presented to the king of France, on February 28th, 1701, an exact translation of which will constitute the most faithful account we can give. "The design of this piece of workmanship," says the author, "is the construction of an armillary sphere, which, by the motion of its circles, may imitate those of the heavens, particularly of the primum mobile of the sun and moon, and imitate, by a sensible resemblance, the apparent situation of heaven at every moment.

"The primum mobile makes its revolution in 24 hours from east to west upon the poles of the world, by means of a movement which is below the equinoctial polar dial-plate. The equator is divided into 360° ; and the zodiac, upon which are marked the signs, is pierced (in the middle we suppose), that its breadth may not conceal the sun and moon.

"The heaven is composed of three large circles, namely, the ecliptic and two meridians. The body of the sun is attached to a point of the common section of the meridian with the ecliptic. The ecliptic, turning upon its centre according to the order of the signs, carries the sun, and makes him perform a revolution through the ecliptic in 365 days; and at the same time the heaven is carried by the primum mobile from east to west in 24 hours. The heaven of the moon is also composed of three circles, like that of the sun; but the poles are five degrees removed from those of the ecliptic. The moon, turning upon the poles of her heaven, moves through the zodiac, according to the order of the signs, in the space of one lunar month, and in 24 hours from east to west upon the poles of the primum mobile. The body of the moon is of silver, of a spherical shape, one-half of which is darkened, and, presenting the illuminated half always to the sun, shews the phases. The moon's circles carry her from west to east in twenty-nine days and a half, to make a lunar revolution from one conjunction to another.

"In the middle of the sphere there is a little globe which represents the earth: this globe is immovable, and Paris is constantly on its zenith. The meridian is divided two ways into degrees, which begin at the equator and end at the two poles, upon which the primum mobile turns. The equinoctial dial consists of two plates; that in the middle has the hours, and is immovable; the other, which contains the names of the principal cities of the world, is carried by the primum mobile in 24 hours; and one may see at any instant what hour it is at each city which is marked. On the immovable plate is seen the hour of the sun's rising and setting. The horizon carries two concentric circles, on which are marked the signs, and their corresponding days of the month. There are also the names of the winds and their divisions. Upon the stand of the sphere are put the allegorical figures which represent the four elements. The diameter is two feet."

Such is the account given by Alexander of Martinot's armillary sphere, to which he has annexed the following observation. "The motion of this sphere," says he, "is not very exact, because the sun's period is only 365 days, and wants almost six hours in a year. The motion of the moon, too, is performed in $29\frac{1}{2}$ days; so that it wants 44 minutes in a lunation; and in less than three years this quantity amounts to more than a day."

Whether the motion of the sun in this sphere was considered as *real* or only *apparent*, does not appear certain from the account which is here given. In accommodation to natural appearances, we still, it is true, continue to speak

of the sun's place in the ecliptic; and the idea of the sun's performing an annual journey through the heavens is countenanced by the language of our poets; but in all cases it will be allowed, that an instrument ought to exhibit the system which it professes to illustrate, in a manner which cannot mislead the uninstructed. The inventor of the armillary sphere before us, we are disposed to believe, like Martin and Parke in our own time, affected to discredit the Copernican system.

Pigeon's Sphere.—Nearly about the same time with Martinot, M. Jean (or John) Pigeon constructed a sphere, in which the planets were introduced and kept in motion by clockwork: the account which M. Saverieu has given of this instrument in his "Dictionnaire des Mathématiques," makes it rank much higher in our estimation than the last we examined, and it is much to be regretted, that the numbers of the wheelwork have not been transmitted to us. The author expresses himself to this purpose: "Many ages have past over, before we have found ourselves in a situation to execute the plan of the sphere of Archimedes. It is not till our own days that a sphere in motion has been seen, for which we are indebted to the skill of our ingenious artist, M. Jean Pigeon. His sphere is eighteen inches in diameter, and elevated to the height of five feet four inches by a support, from the summit of which is suspended a pendulum: in the middle of the sphere stands the representative of the sun, which is a large gilt ball, and all the planets are attached to their orbits in respective order. Thus, Mercury is the nearest to the Sun, next moveth Venus, then the Earth, Mars, Jupiter, and Saturn. A pendulum gives motion to all the planets, and conducts them within the sphere, according to the order of the signs around the sun as their common centre. The earth turns upon its axis in 24 hours, and also makes the tour of the zodiac, according to the order of the signs, in $365^d 5^h 49^m$. Around the earth is a little circle which represents the ecliptic, so that one may judge in what sign any planet is, and whether its declination be north or south. This circle also serves to ascertain the retrogradations, direct motions, and stations of the planet. There are also two other small circles round the earth, one of which represents the horizon, and the other the meridian, which is adjustable to any place on the earth. To the orb of this planet is attached an index, pointing towards the sun, the use of which is to mark the times of the new and full moons; another index is placed below the moon to mark her latitude upon a plate, on which are marked the nodes, called the *head* and *tail* of the *dragon*, by means of which one may see if the moon be at any time in the ecliptic, &c."—From this description of Pigeon's sphere, it seems to have been the most comprehensive representation of the Copernican system of any which we have hitherto met with, inasmuch as the diurnal motion of the earth, and the motion of the moon's nodes, have been added to the revolutions of the planets. All the motions, we must conclude, were mean motions, and as nothing is said about the wheelwork, we know not how far these motions were accurate. The plan, however, seems to have been happily conceived, and well calculated to produce a pleasing object to the eye of a spectator.

Orrery by Graham and Rowley.—We have now come down to the time when our own country produced in a machine a combination of the annual and diurnal motions of the earth, together with the motions of the moon and primary planets, and gave to such combination the name of *Orrery*, in honour of the earl of Orrery, who at that time patronized the sciences; but as we have described this complex mechanism with considerable minuteness under our article ORRERY, it would be superfluous to say more

PLANETARY MACHINES.

in this place, than that the date alluded to was about the year 1715.

A Sphere moving by Clockwork, calculated by M. Passémant, and constructed by Dauthiau, Clock-maker to the King of France.—As this machine appears to be much superior to any of the preceding ones, both in accuracy and extent, it claims a detailed notice, which cannot be given more faithfully than by translating the abridged description given by Ferdinand Berthoud, from a small pamphlet of Dauthiau, published at Paris in 1756, in duodecimo.

“This clock, which is surmounted by a sphere, which it puts in motion according to the Copernican system, was presented to the Academy of Sciences on the 23d of August 1749, by M. Passémant, the author of the calculations of the sphere, to which he applied himself about 20 years. The gentlemen of the academy, from the report of Messrs. Camus and Deparcieux, the committee named for the examination of this clock, have certified that the revolutions of the planets are exact in it; for that they did not find a degree of difference from the astronomical tables in less than 3000 years. Dauthiau, the clock-maker, who constructed this machine, employed twelve years upon it. It was presented to the king at Choisy on the 7th of September 1750. His majesty, being a protector of the sciences and arts, testified his satisfaction of it, and ordered a new case to be made for it after a design of his own choice, which was executed by Messrs. Caffery, father and son, after which it was again presented to the king at Choisy, the 20th of August 1753, and thence sent to Versailles.

“The sphere represents from day to day the different motions of the planets round the sun, *i. e.* of Saturn, Jupiter, Mars, the Earth, Moon, Venus, and Mercury, also their places in the zodiac, their configurations, stations, and apparent retrogradations with respect to the earth. Upon every circle which carries the orb of a planet, is engraven the time of its revolution round the sun. The earth, during its annual revolution, makes its movement of parallelism, and views the sun passing through the signs and degrees of the zodiac; also through the months and their day spaces, (quantièmes,) indicating the seasons, the equinoxes, and solstices; besides, it makes a rotation in 24 hours, being divided by 24 meridian lines: it has likewise a map of the principal places of the globe; so that the rising, setting, and meridian passage of the sun, together with his different elevations, and the continuance of day and night, may be seen for every principal place. The moon finishes her revolution round the earth in 29^d 12^h 44['] 3^{''}, during which time are indicated her age and different phases; her progress through the signs of the zodiac; her nodes, her eclipses, and those of the sun with precision, *viz.* their place, size, and duration; besides the various altitudes, and times of rising, setting, and southing.

“The clock beats seconds, which are indicated in the centre of the dial-face by a dead-beat escapement (*échappement à repos*) of a particular construction. This clock effects the equation by itself, by shewing both apparent and mean time (called by the French “*le temps vrai et le temps moyen*,” which, in England, mean the same thing); it strikes the hours and the quarters of solar time, which it will repeat at pleasure. The movement of the striking part is by a spring, *sûrte*, and chain, that of the clock by a weight of twenty pounds doubly-suspended, which has a descent of eight inches in six weeks, and the going is not interrupted by winding up the weight. The pendulum rod consists of bars of steel and brass, adjusted so as to keep the metallic lens always at the same distance from the point of suspension by the difference of their expansions; and by this difference a hand is made to point out the variation of tem-

perature on a divided circle on the top of the rod, which forms therefore a natural thermometer by the sole action of metals.

“On the front of the clock, over the face, is a planisphere marking the age and phases of the moon; in which are, besides the day of the week, the names and days of the month, and year spaces after a new and singular method; for though some months have 28, 30, and 31 days each, yet the clock makes February to have 29 days every fourth year for bissextile. The mechanism for shewing the days of the year will point them out for ten thousand years, if the clock will wear so long, by means of four indexes revolving respectively in 10, 100, 1000, and 10,000 years.”

In this clock and sphere are three contrivances for disengagement; the first for the escapement; the second for the sphere to be detached from the clockwork to move by a handle; and the third for detaching the diurnal motion of the earth, that the planets may have a quick motion by means of a corresponding handle. Thus the different portions may be disengaged from each other to make the necessary rectifications. The number of wheels and pinions employed in this mechanism are 60, some of which are in the interior part of it; the diameter of the sphere is one foot, and is surrounded by a cover of glass; the case of the clock is d’or moulu, with four faces, having glass covers, neatly designed, well finished, and exposed so far to view, that all the mechanism may be seen: the whole height from the top of the sphere is seven feet.

According to the report of Antide Janvier, who was employed to repair this instrument, previously to its being placed in the gallery (of the first consul) at the palais des Thuilleries at Paris, in the year 8, the following are the numbers of the wheels and pinions which are put down in his own method of noting them, and also their respective values in time.

The periodic revolution of the Moon from a motion of 48 hours.

$$\left. \begin{array}{l} \text{Pinions } 72 \cdot 25 \cdot 20 \cdot 41 \cdot 20 \\ \text{Wheels } 75 \cdot 54 \cdot 44 \cdot 31 \cdot 73 \end{array} \right\} = 27^{\text{d}} 7^{\text{h}} 43' 4'' 58'''.$$

Revolution of Mercury from a motion of 27 days 7 hours, &c.

$$\left. \begin{array}{l} \text{Pinions } 31 \cdot 85 \\ \text{Wheels } 84 \cdot 101 \end{array} \right\} = 87^{\text{d}} 23^{\text{h}} 14' 15'' 56'''.$$

Annual revolution of the Earth from a motion of 87 days 23 hours, &c.

$$\left. \begin{array}{l} \text{Pinions } 8 \cdot 35 \cdot 83 \\ \text{Wheels } 43 \cdot 44 \cdot 51 \end{array} \right\} = 365^{\text{d}} 5^{\text{h}} 48' 58'' 3'''.$$

Revolution of Venus from a motion of 365 days 5 hours 48 minutes, &c.

$$\left. \begin{array}{l} \text{Pinions } 53 \cdot 76 \\ \text{Wheels } 42 \cdot 59 \end{array} \right\} = 224^{\text{d}} 16^{\text{h}} 40' 30''.$$

Revolution of Mars from a motion of 365 days 5 hours 48 minutes, &c.

$$\left. \begin{array}{l} \text{Pinions } 53 \cdot 75 \\ \text{Wheels } 84 \cdot 89 \end{array} \right\} = 1^{\text{y}} 321^{\text{d}} 16^{\text{h}} 32' 11''.$$

Revolution of Jupiter from a motion of 365 days 5 hours 48 minutes, &c.

$$\left. \begin{array}{l} \text{Pinions } 9 \cdot 45 \\ \text{Wheels } 49 \cdot 98 \end{array} \right\} = 11^{\text{y}} 312^{\text{d}} 22^{\text{h}} 28' 0''.$$

Revolution of Saturn from a motion of 365 days 5 hours 48 minutes, &c.

$$\left. \begin{array}{l} \text{Pinions } 7 \cdot 40 \\ \text{Wheels } 80 \cdot 103 \end{array} \right\} = 29^{\text{y}} 156^{\text{d}} 12^{\text{h}} 46' 40''.$$

Revolution of the Moon, with respect to the node, from a motion of 29 days 12 hours 44 minutes 3 seconds.

$$\left. \begin{array}{l} \text{Pinions } 50 \cdot 67 \\ \text{Wheels } 49 \cdot 63 \end{array} \right\} = 27^{\text{d}} 5^{\text{h}} 5' 36''.$$

N. B. Each dot between the figures in the above examples is a sign of multiplication.

PLANETARY MACHINES.

“It may be asked,” says Janvier, in a note to his report, „ where is the revolution of $29^d 12^h 44' 3''$ which gives motion to this last movement, it being not contained in the preceding statement; but we have seen the periodic revolution, which consists of the time in which the moon goes round the heavens; that interval, we know, is shorter than a synodic revolution; but this (synodic) revolution has no real existence, but by means of the earth's change of situation, whose orbit carries a wheel immoveably fixed at the centre of the moon's orbit, round which the moon revolves really in $29^d 12^h 44' 3''$; it is this wheel, then, which gives motion to the wheelwork which represent the eclipses with great accuracy. The last wheel of this movement carries a small dial-plate on which the moon shews her position with respect to the node; this dial carries besides an excentric piece, which makes the moon's place above and below the plane of the ecliptic within the limits of her greatest latitude.

“The dial of the nodes is placed vertically, it accompanies the moon, and turns round the earth at the same time that it makes a revolution round its centre in the period we have specified. This peculiarity has rendered the calculation singularly complex, and the effect less convenient to observe. Notwithstanding this defect, this function is one of those which shews a greater genius than that of Paffemant; it was necessary to be better acquainted with astronomy than

the rest of the parts demand, to devise a similar disposition of parts, which it is impossible to comprehend without figures.”

P. le Roi, speaking of this sphere, says “the calculations are so exact, that one could hardly imagine it possible to arrive at such accuracy.”

Such are the ample notices which we have procured of this instrument; but notwithstanding the accuracy of the mean motions above stated, it must be recollected that, as the equations of the centre and excentricity are not attempted to be represented, nor even the relative distances, the conjunctions, oppositions, stations, and retrogradations will be far from accurate in respect to the *times* of their appearance; besides, the want of the five last discovered planets renders it otherwise at this time incomplete.

In the account which has been here translated, it does not appear whether the *year* mentioned in the periods of Mars, Jupiter, and Saturn, is a solar or civil year of $365\frac{1}{4}$ days, or whether it is taken at 365 exactly; we will therefore go through all the calculations again according to our own method, which, though attended with some trouble, (see NUMBERS, *Planetary*,) will afford us the satisfaction of knowing the precise value of each movement in days and parts of a day. The whole work abridged will stand thus: *viz.*

			D. H. M. S.
Moon's period	$\frac{75}{72} \times \frac{54}{25} \times \frac{44}{20} \times \frac{31}{41} \times \frac{73}{20} = \frac{403266600}{29520000}$ of $2^d =$		27 7 43 4.96932
Mercury's revolution	$\frac{84}{31} \times \frac{101}{85} = \frac{8484}{2635}$ of $27^d.3215853 =$		87 23 14 16.4976
Earth's revolution	$\frac{43}{8} \times \frac{44}{35} \times \frac{51}{83} = \frac{96492}{23240}$ of $87^d.9682465 =$		365 5 48 59.04048
Venus' ditto	$\frac{42}{53} \times \frac{59}{76} = \frac{2478}{4028}$ of $365^d.2423507 =$		224 16 40 28.408
Mars' ditto	$\frac{84}{53} \times \frac{89}{75} = \frac{7476}{3975}$ of ditto =		686 22 21 23.76
Jupiter's ditto	$\frac{49}{9} \times \frac{98}{45} = \frac{4802}{405}$ of ditto =		4330 14 26 43.64
Saturn's ditto	$\frac{80}{7} \times \frac{103}{40} = \frac{8240}{280}$ of ditto =		10748 4 52 59.20
Moon's node	$\frac{49}{50} \times \frac{63}{67} = \frac{3087}{3350}$ of $29^d.53059 =$		27 5 5 32.67

From these calculations we find that the *solar* year is the year intended, as mentioned in the periods of Mars, Jupiter, and Saturn, which year is made by the wheelwork 11" longer than La Lande's tables make it. The revolutions of the planets in his machine are tropical, and, though not so accurate as they might have been calculated in a shorter time than *twenty years*, yet are they more accurate than in any other machine which preceded it. The period of Saturn, which is the most inaccurate, is pretty nearly equally distant from that of Dr. Halley and that of La Lande.

Paffemant's Planetary Clock.—Besides the preceding machine of M. Paffemant, this author invented a clock in the year 1754, which has a case of five feet in height, and which gives motion to a terrestrial globe of four inches in diameter, on which the different countries are engraven, and which is placed in the midst of artificial rocks and waterfalls that serve as an universal horizon: at some distance is represented the sky, containing a sun of three feet diameter, and all the primary planets in motion round him, according

to their respective velocities, and the four nearest according to their proportional distances; the excentricities and alternate increase and decrease of velocity at the perihelion and aphelion points are also effected, and all the phenomena depending upon the earth's parallelism and diurnal rotation are accurately represented. There is also a moon performing a lunation, and all her various phases in the sky, in a natural manner. F. Berthoud has given his abridged notice of this clock from “Description et Usage des Telescopes,” a work published at Paris by Paffemant in 12mo.; but as there is no account given of the numbers of the wheelwork, nor other particulars of the construction, we must suppose that the numbers of the preceding machine were adopted: the clock is said to have been made for the king of Golconda, and to be still in existence at Paris. It is matter of regret that we have it not in our power to describe by what contrivance the excentricity of each orbit is effected.

Astronomical Machine by Phil. Mat. Hahn.—If we pass over the days of Benjamin Martin and James Ferguson, whose

PLANETARY MACHINES.

whose astronomical mechanism has in part been explained under our article ORRERY, and is to be found in their works in almost every one's hands, we meet with no original machinery of any importance till we arrive at the year 1791, in which a description was published in a pamphlet, in London, of a planetarium or astronomical machine, invented and partly executed by Phil. Mat. Hahn, member of the Academy of Sciences at Erfurt, and completed by Albert de Mylins.

This machine consisted of three several portions, which were actuated by a pendulum clock, and which composed three different systems; viz. 1st, the solar system of seven primary planets; 2dly, the particular planets only which have secondaries, in which those secondaries have their motions given by wheelwork as well as their primaries; and 3dly, a celestial sphere of copper, with 1500 stars engraved on it, in which were contained about 100 wheels that gave motion to the planets as they appeared when viewed from the earth. All these motions are said to have been produced by trains of wheelwork that were calculated with the greatest accuracy, but as the numbers have not been disclosed that compose the teeth of those wheels, we cannot form an estimate of their accuracy; neither can we gratify our readers with an account how the inequalities of motion were produced, according to which several of the planets are stated to have moved. The whole fabric was of the best workmanship, and its different portions were so symmetrically arranged, that it was deemed a handsome present to be taken by lord Macartney in his capacity of ambassador to China, where probably its uses will not be duly appreciated.

Planisphere and Sphere by Antide Janvier of Paris.—A. Janvier, whose new orrery we have described in its place, received his mechanical and mathematical instructions from l'Abbé Tournier, who maintained a system of astronomy in some respects similar to that of Ptolemy; and during the early part of his life the pupil employed himself in representing, by means of wheelwork, the planetary system of his master, as seen from the earth as the centre of all the apparent motions. The terrestrial globe, placed in the middle of the system, was made to have the diurnal motion, while the sun was made a planet, with his secondaries, Mercury and Venus, beyond the orbit of the moon, which was considered as the first planet. The other planets had their

periodic revolutions in their respective times; but, to represent the retrogradations and stations, a second arm was made to revolve at the point of mean distance, in the same direction as the radius vector of each planet, once in each *synodic* revolution, as they regarded the sun, each short arm being made equal to the radius vector of the sun. This arrangement produced the geocentric appearances so well, that the author of the system pertinaciously withstood all the arguments of Cassini in favour of the Copernican system; and a perusal of it has probably laid the foundation of what has very recently been denominated the *Martian* system by a pretender, who is endeavouring, in our own time, to institute a *Society*, under royal patronage, for the defence of his system, as compared to that of Copernicus and sir Isaac Newton! Janvier, however, was soon convinced that the system of his preceptor was erroneous, and in the year 1789 he began the construction of a sphere that was to include the motions of the planets agreeably to the Newtonian system, and that was finished in the year 1801, after a period of eleven years spent in the calculations and construction. The sphere is mounted on a pillar with four faces, in the interior of which pillar are concealed a great variety of wheels and pinions, that are put in motion, like Hahn's machine, by a seconds' pendulum clock of the best construction. To these four faces are attached several dials and corresponding hands to indicate the various phenomena of the planets that are exhibited within the sphere, where the heavenly bodies are in motion. It would not be possible to give such a verbal description of this machine as would enable the reader to comprehend the peculiarities of its construction, without several plates for the representation of the respective parts; but we will not conclude our present article without giving an abridged account of its leading features. The trains of wheelwork contained within the pillar, and giving motion to the hands, have each six or eight wheels and pinions, from which consequently great accuracy may be expected; but those that actuate the planets within the sphere are not so numerous, and consequently not so accurate; so that the indication of the phenomena is more exact than the occurrence of those phenomena. The wheels and pinions that are principally employed, and the periods corresponding to the respective trains, may be put down thus:

The Tropical Revolutions.

				D. H. M. S.
Mercury	-	$\frac{80}{10} \times \frac{140}{43} \times \frac{179}{53}$	of 24 hours =	87 23 14 30
Venus	-	$\frac{62}{7} \times \frac{81}{17} \times \frac{197}{37}$	of ditto =	224 16 41 25
Earth	-	$\frac{52}{7} \times \frac{61}{13} \times \frac{241}{23}$	of ditto =	365 5 48 49 $\frac{1}{10}$
Mars	-	$\frac{89}{6} \times \frac{137}{6} \times \frac{144}{71}$	of ditto =	686 22 18 35
Jupiter	-	$\frac{57}{6} \times \frac{72}{6} \times \frac{89}{6} \times \frac{105}{41}$	of ditto =	4330 14 38 2
Saturn	-	$\frac{82}{4} \times \frac{92}{6} \times \frac{92}{8} \times \frac{110}{37}$	of ditto =	10476 19 14 35
Georgian	-	$\frac{60}{6} \times \frac{73}{6} \times \frac{97}{6} \times \frac{108}{7}$	of ditto =	30347 3 25 43
Moon	-	$\frac{23}{5} \times \frac{37}{20} \times \frac{61}{19}$	of ditto =	27 7 43 4-4

PLANETARY MACHINES.

The Synodic Revolutions.

			D. H. M. S.
Mercury	-	$\frac{24}{6} \times \frac{27}{8} \times \frac{103}{12}$ of 24 hours	= 115 21 5 37
Venus	-	$\frac{19}{4} \times \frac{53}{4} \times \frac{167}{18}$ of ditto	= 583 22 5 0
Jupiter	-	$\frac{132}{6} \times \frac{158}{61}$ of 7 days	= 398 19 12 54
Moon	-	$\frac{58}{15} \times \frac{65}{22} \times \frac{137}{53}$ of 24 hours	= 29 12 44 2.87
Ditto	-	$\frac{19}{235}$ of 365.24222	= 29 12 43 31
1. Satellite of 24		$\frac{4}{3} \times \frac{76}{31} \times \frac{98}{181}$ of 24 hours	= 1 18 28 35.6
2. Ditto	-	$\frac{11}{6} \times \frac{13}{6} \times \frac{19}{17}$ of ditto	= 3 13 17 54.7
3. Ditto	-	$\frac{63}{19} \times \frac{67}{31}$ of ditto	= 7 3 59 35.55
4. Ditto	-	$\frac{61}{4} \times \frac{78}{71}$ of ditto	= 16 18 5 4.2

The Moon's Apogee.

From 24 ^h	-	$\frac{69}{6} \times \frac{127}{8} \times \frac{177}{10}$	= 3231 8 33 0
From 27 ^d 7 ^h 43 ^m		$\frac{57}{10} \times \frac{74}{13} \times \frac{113}{31}$	= 3231 8 44 0
From 365 5 48 49 ^s		$\frac{93}{98}$, viz. $\frac{93}{98-93}$	= 19 $\frac{1}{2}$ years

The Moon's Node.

From half synodic revolution of the Moon		$\frac{106}{25} \times \frac{259}{59}$	= 6798 5 0 0
From 365 ^d 5 ^h 48 ^m 49 ^s	-	$\frac{115}{102}$, viz. $\frac{115}{115-102}$	= 8 $\frac{1}{3}$ years.

Besides these trains of wheelwork, there is one that converts mean solar into sidereal time, the numbers of which are these, viz. $\frac{19}{29} \times \frac{67}{40} \times \frac{239}{63} = \frac{304247}{305085}$, the difference

between the numerator and denominator of which large fraction is 833; the acceleration of sidereal on solar time is, therefore, $\frac{86400'' \times 833}{305085} = \frac{2160 \times 833}{7627} = 3' 55'' 54'''$

$33''' 40''''$; and the time required for its accumulation into 24^h will be very nearly 365^d 5^h 48^m 49^s. There are various ingenious contrivances in the construction of this machine, that attest the mechanical skill of the inventor, but which cannot be intelligibly described without drawings: the principal of them are the manner in which the diurnal train is made to act; a representation of the two separate causes of the equation of time; and an union of the grand equation, of the evection, and of the heliocentric latitude of the moon, in every part of her orbit. In both the planisphere and the sphere there are some complex calculations introduced, in order that the periods, which would be altered by the mode in which the wheels are placed for action, may be rectified by corresponding alterations in the numbers of the wheels,

after the original calculations were made. But accurate as the trains in general are, we are of opinion that, in many cases, fewer wheels would have effected equal accuracy in the periods, particularly in that of Georgian, which is very erroneous; and as the four newly-discovered planets are left out, the machine cannot be called perfect at the present moment, notwithstanding the great pains that have been bestowed upon its construction for the continued space of eleven years. A memoir of this elaborate machine was laid before the National Institute of France, through the medium of Coulomb, Delambre, and Fred. Berthoud, which the last named has copied into his "Histoire du Temps," together with the various drawings, which the curious reader may consult with advantage, who wishes to make himself master of all the particulars of the construction.

In this historical sketch we might have introduced notices of other machines, such as the orrery of Ribright in the Poultry, of Dean in Dublin, and of Bolton, belonging to her majesty, at Windsor, if we had been aware that there is any thing peculiar in the construction of any of them; and with respect to the pendulous orrery of Rittenhouse in Philadelphia, and to that lately exhibited at the Pantheon, London, as well as to Mr. Walker's eidouranon, and Mr. Lloyd's diaastrodoxon, we consider these not as objects of

close

close examination, but as conveying only general information by a scenic effect, not depending on the accuracy of the wheelwork, and therefore not claiming our minute attention. For an account of those modern machines, which appeared to us to merit a more particular description than we could allot them in this article, we must request the reader to consult our articles ORRERY, PLANETARIUM, and SATELLITE Machine.

PLANETARY Dials, those whereon the planetary hours, latitudes, or equations, are inscribed. See DIAL, ORRERY, and PLANETARIUM.

PLANETARY Globe. See GLOBE.

PLANETARY System, is the system or assemblage of the planets, primary and secondary, moving in their respective orbits round their common centre, the sun.

PLANETARY Squares, the squares of the seven numbers from 3 to 9, disposed magically.

Corn. Agrippa, in his famous book of magic, has given the construction of the seven planetary squares: M. Poignard, canon of Brussels, in his Treatise of Sublime Squares, gives new, easy, and general methods for making the seven planetary squares, and all others to infinity, by numbers, in all sorts of progressions. See MAGIC Square.

PLANGESTA, in *Geography*, a town of Bengal; 21 miles N.N.W. of Kishenagur.

PLANIARY, a town of Bohemia, in the circle of Kaurzim; 3 miles N.N.E. of Kaurzim.

PLANIER, a small island in the Mediterranean, near the coast of France. N. lat. $43^{\circ} 12'$. E. long. $6^{\circ} 19'$.

PLANIFOLIOUS FLOWERS. See FLOWER.

PLANIMETRY, PLANIMETRIA, that part of geometry which considers lines and plain figures; without any consideration of heights or depths.

Planimetry is particularly restrained to the mensuration of planes or surfaces; in opposition to *stereometry*, or the mensuration of solids. See MEASURING and SURVEYING.

Planimetry, or the art of measuring the surfaces and planes of things, is performed with the squares of long measures, as square feet, square inches, square yards, square perches, &c.; that is, by squares whose sides are an inch, a foot, a yard, a perch, &c.; so that the area or content of any surface is said to be found, when we know how many such square inches, feet, yards, &c. it contains.

PLANING MACHINES, are machines used to diminish the great manual labour of planing the surface of planks and boards of wood: in strictness, those alone should be termed planing machines, which operate to reduce the surface of the wood to a true and smooth plane, by means of planes or instruments of a similar nature, though actuated by the power of machinery instead of the strength of a man's arm; but custom has denominated those machines which cut flat surfaces in a different manner from planes by the same name.

These machines are of modern invention; the first, we believe, was projected by general Bentham, who obtained a patent for it in 1791. It consisted of a plane, to be put in motion by means of a crank turned by a mill, to give it a reciprocating motion; or on a smaller scale it might be worked by hand in the usual manner, but the plane was so formed as to require none of the skill and attention necessary in the ordinary method of operating: here the workman, besides exerting the force necessary to force the instrument along, has several points to attend to, even in the simple case of planing a straight board he must adjust his tool to the board in a proper manner for beginning the stroke, and employ sufficient force to keep it down to the board; and in returning, he must raise it up off the board sufficient to save the cutting edge from injury; he must also guide it side-

ways to prevent it slipping off the board, and if this is wider than the plane, he must constantly examine if he reduces the middle and the sides in a proper manner to make a plane surface; and, lastly, he must observe the marks he previously makes for the thickness of the board, that he may keep it parallel, and not reduce it too thin. By the general's invention all these circumstances are gained at once; the plane is made the full width of the boards intended to be planed, and on each side of it fillets or checks are fixed, which project beneath the face of the plane just as much as the thickness the board is to be reduced to: these checks, therefore, guide the plane sideways in passing along the board, and gauge it in thickness; because, when the board is reduced to the quantity which the checks are beneath the surface of the plane, the checks rest upon the bench or surface on which the board lies, and bear off the plane, so that it can cut no longer. The plane is kept down by its own weight, which is increased, when necessary, by loading it with weights, and these are contrived to be capable of shifting their position from one end of the plane to the other during the time it is making the stroke; because, at first the pressure is required at the fore end to enter the cut, but at the conclusion it must be greatest at the hinder end, to prevent the fore end tripping down the instant it leaves the board. By another contrivance the plane is caused to rise up sufficiently to clear the cutting edge from the wood when the plane is on its return. It is by a piece which acts as a handle to the plane, and to which the power is applied, that it is fixed in the manner of a lever upon an axis extending across the width of the plane, and carrying at each side thereof a short lever, provided with rollers in their extremities; the handle projects upwards from the plane, which being forced forwards by it, assumes an inclined position, as do also the short levers, and their rollers then rise above the checks of the plane; but when the plane is drawn back, its handle is first drawn back into an erect position, and the levers moving with it, their rollers project beneath the checks of the plane, and raise it off the bench, the plane being in its return borne by them.

The bench for supporting the board during the operation was also of a peculiar construction, in order to confine the work steady upon it. In cases when the boards to be planed are winding or irregular on the lower side, so that they cannot lie flat upon the bench, it is provided with two sides, which can be brought to close upon the edges of the board, and hold it steady between them, being furnished with one or more rows of flat teeth to penetrate the wood and retain it; these sides are contrived to rise or fall upon the bench, to accommodate the different thicknesses of the boards. When a very thin board is to be planed, it might be liable to spring up to the iron, so as to be reduced even after the plane came to rest with its checks upon the bench; to avoid this the edges of the board are to be held by the sides to the bench above-mentioned, but as it would still be liable to spring up in the middle part, heavy rollers, or rollers loaded with weights, are fitted in apertures made in the plane as near as possible to the cutting edge, and these will keep the board down close upon the bench. For planing pieces of greater thickness at one end than the other, the checks of the plane are to be borne upon rulers of wood laid on the bench on each side, the wood being as much thicker at one end as the board is intended to be thinner at that end; therefore, when the plane has reduced the wood, the checks come to bear upon these rulers, and cause it to move not parallel to the bench, but inclined, according as they are thicker at one end than the other: in like manner, by using them of different thicknesses at the different sides the boards may be made feather-edged.

Mr. Bramah invented a planing machine, which he has used

PLANING MACHINE.

used very advantageously for planing all kinds of timber flat, at an exceedingly small expence. In 1802 he took out a patent for the invention, which he describes in his specification to consist in the following particulars. "The cutting tools employed to reduce the wood, instead of being worked by hand are to be fixed on frames, some of which are moved in a rotatory direction round an upright shaft, and others have a shaft lying in a horizontal position like a common lathe. In other instances, the tools are fixed on frames, which slide in stationed grooves to be driven also by machinery. The principal points on which the merits of the invention rest are, 1. The materials to be wrought are made to slide in contact with the tool, instead of the tool being carried by the hand over the work in the usual way. 2. The tool is made to travel across the work in a square or oblique direction, except in cases where it may be necessary to fix the tool in an immoveable station, and cause the work to fall in contact with it by a motion. 3. Instead of common tools, bent knives, spoke shaves, or deep cutting gouges, are used for cutting off the roughest parts, and planes of various shapes and constructions, as the work may require, are applied to follow the former in succession, under the same operation, and which latter I call finishers. 4. These are fixed on frames which move in cases, like those on which the saws are fixed in a sawing-mill, and in other instances these frames are fixed on a rotatory upright shaft turning on a step, and carrying the frame round in a direction similar to the upper millstone for grinding corn, and sometimes the frames turn on a horizontal shaft, resembling the mandrel of a common turning lathe. The different planes, tools, &c. are fixed in the frames, so as to fall successively in contact with the wood or other materials to be cut, so that the cutter or tool calculated to take the rough and prominent part operates first, and those that follow must be so regulated as to reduce the material down to the line intended for the surface. These cutter frames must also have the property of being regulated by a screw, or otherwise, so as to approach nearer the work, or recede at pleasure, in order that a deeper or shallower cut may be taken at discretion, or that the machine may repeat its action, without raising or depressing the material on which they act. 5. When an upright shaft is used, the pivot is to turn in oil, and it may be raised or depressed at pleasure, by means of a greater or less quantity of the said fluid being confined between the end of the shaft and the bottom of the step. 6. The materials to be cut must be firmly fixed on a frame, similar to those in sawing-mills, on which the timber is carried to the saws. These frames must be moved in a steady progressive manner as the cutter frame turns round, either by the same power which moves the latter, or otherwise, as may be found to answer best in practice. 7. The motion of the cutter frames must be under the controul of a regulator, so that the velocity of the tool, in passing over the work, may be made quicker or slower as such work may respectively require, to cause the cutter to act properly to the best advantage." For this purpose Mr. Bramah proposes to use what he calls a universal regulator of velocity, and which he describes as follows: "I take any number of cog-wheels, of different diameter, with teeth that will exactly fit each other through the whole; suppose ten, or any other number, but for an example say ten, the smallest of which shall not exceed one inch in diameter, and the largest suppose ten inches in diameter, and all the rest to mount by regular gradation in their diameters from one to ten. I fix these ten wheels, fast and immoveable, on an axis perfectly true, so as to form a cone of wheels; I then take ten other wheels, exactly the

same in all respects as the former, and fix them on another axis, also perfectly true, and the wheels in perfect gradation also; but these latter wheels I do not fix fast on their axes, like the former, but leave them all loose, so as to turn upon the said axes, contrary to the former, which are all fixed. All these latter wheels I have the power of locking, by a pin or otherwise, so that I can at discretion lock or unite any single wheel at pleasure to the axis. I then place the two axes parallel to each other, with the wheels which form the two cones as above described, in reverse position, so that the large wheel at one end of the cone may lock its teeth into the smallest one in the cone opposite, and likewise *vice versa*. Then suppose the axis, on which the wheels are permanently fixed, to be turned about all the wheels on the other axis will be carried round with velocities correspondent to their diameters and those of the former, but their axes will not move. Then lock the largest wheel on the loose axis, and by turning about the fastened axis, as before, it must take ten revolutions, while the opposite wheel performs but one; then by unlocking the largest wheel, and locking the smallest one at the contrary end of the cone in its stead, and turning as before, the fastened axis will then turn the opposite ten times, while itself only revolves once. Thus the axes or shafts of these cones, or conical combinations of wheels, may turn each other reciprocally, as one to ten, and ten to one, which collectively produces a change in velocity, under an uniform action of the primum mobile, as ten to a hundred; for when the small wheel on the loose axis is locked, and the fast one makes ten revolutions, the former will make one hundred; and by adding to the number of those wheels and extending the cones, which may be done *ad infinitum*, velocities may be likewise infinitely varied by this simple contrivance: A may turn B with a speed equal to thousands or millions of times its own motion; and by changing a pin and locking a different wheel, as above described, B will turn A in the same proportion, and their power will be transferred to each, in proportion as their velocities reciprocally. Here is an universal regulator at once for both power and velocity. In some instances I produce a like effect, by the same necessary number of wheels made to correspond in conical order, but instead of being all constantly mounted on the axes or shafts, as above described, they will reciprocally be changed from one axis to the other, in single pairs, to match according to the speed or power wanted, just as in the former instance. This method will have, in all respects, the same effect, but not so convenient as when the wheels are all fixed."

The utility of Mr. Bramah's machine, not less than its ingenuity, has induced us to procure drawings of one of them, which he has in constant use in his factory at Pimlico. It is upon exactly the same construction as one he made for the royal arsenal at Woolwich, by which all the timber for gun-carriages, and other similar articles, is now planed at a trifling expence, compared with the old method of planing by hand labour. See *Plates I. and II. Planing Machine*, where *fig. 1.* is a plan of the whole machine, and *fig. 2.* an elevation thereof; *A a* is a vertical axis, put in motion by a steam-engine, the power being communicated to it by a pair of bevelled wheels *B*, one fixed on the vertical shaft, and the other at the extremity of a horizontal spindle *C*, *fig. 1*; see also *fig. 8. Plate II.* which has a live and dead pulley upon it at *c*, for the reception of an endless strap, by which the machine is driven. The shaft *a A* is for the purpose of carrying an iron wheel *33*, shewn separate in *fig. 3*; it has the cutters fixed at the different points *7, 7, 7, 7*, of its circumference; these

PLANING MACHINE.

these are six in number at each side, and are formed with cutting edges similar to gouges or scoops (see *fig. 7.*); at the two opposite points, 4 and 5, it has small planes fixed in its rim, as shewn separate in *figs. 4* and *5*: when this wheel revolves, its cutters will cut away all which projects above the plane of their motion; the wood is carried under them with a progressive motion, upon two moveable carriages E E and E E, one at each side of the wheel, and moving in opposite directions; they traverse upon iron beds, or railways F, F, which are more than double the length of the carriages: these are supported on iron legs, from a foundation of masonry, and well united together by cross pieces D, D, to keep them always in one plane, for upon this circumstance the truth of the planing depends. The pieces of wood to be planed are fixed down upon the carriages at G, G, and held firmly by screw-clamps with proper contrivances; the machine is then put in motion, and at the same time that the wheel is revolving the carriages are both drawn in opposite directions beneath its cutters, which soon clears away the wood to a perfect plane, by making successive strokes obliquely across the wood, and as the carriages advance these strokes proceed in succession from one end of the piece to the other. The gouges 7, 7, act first to chop, or hew away the wood roughly, but to a flat surface, and then the planes 4, 5, follow and reduce it to a smooth plane: this is accomplished by their being placed rather nearer the centre, so that they revolve in a rather smaller radius, and thus act upon the wood after the gouges have finished. We shall now enter more minutely into the details of the machinery: the two carriages E, E, are put in motion alternately, by means of an endless chain H H, which is extended between two horizontal wheels K, I; the centre pin of the latter is fixed in a piece of wood d, fitted in a groove formed between the two adjacent rails F, F, on which the carriages run; the slider has a screw b, by which it is forced outward, and thus strains the chain between the two wheels so tight, that when the wheel K is turned round, it will draw the chain, which being connected with the carriages beneath, gives them both a progressive motion. The wheel K is fixed upon a short vertical axis, upon the lower end of which is a pinion L, having its teeth engaged with a rack M, attached to the piston-rod of a cylinder 10, situated horizontally on the ground (see also *fig. 10. Plate II.*): the piston-rod, M, is fitted through a stuffing-box, e, at the end of the cylinder, and the piston, f, is fitted accurately to the chamber with leathers, to make it perfectly water-tight: the cylinder is bolted fast down upon the floor framing, as shewn in both figures, and pipes g, b, enter into it at each end, for the purpose of introducing or returning water, which acts upon the piston f, to give it an advancing or retrograde motion, upon the hydrostatic principle invented by Mr. Bramah, and described at the end of our article MACHINERY; see also PRESS, *Hydrostatic.* The steam-engine which gives power to the whole machine also works a small forcing pump, or injector, which is constantly pumping water into an air-vessel, under a great pressure: from this small copper pipes are conducted to the machine, to operate, when required, either in the cylinder 10, or in another, which is the step, or support of the main vertical shaft, and gives the means of raising or lowering it with the wheels and cutters all together, to cause them to reduce the wood upon the bench to any required thickness. The admission of the water into these cylinders is regulated by cocks, situated at one side of the machine, in a position where a person can, at the same time, manage them, and have a complete view of all the machine, to watch its operation. The relative position of these cocks

is shewn in *fig. 8*, where that for the service of the cylinder is marked N, and the other for regulating the thickness is marked O, and i is the pipe leading from it to the bottom of the cylinder 13; the cocks themselves are shewn on a large scale in *figs. 11* and *12*: the entry pipe, which brings the water from the injector, is here plainly shewn, with two branches leading to the cocks. From the cock N, a passage directly opposite to the entry leads to the waste, or escape-pipe; and on the two opposite sides, at right angles to the former, are pipes g and b, leading to the front and back of the cylinder: the cock itself has two curved passages through it, which will make communication with any two adjacent pipes of the four; thus, as it stands in the figure, the water from the entry passes to the back of the cylinder, whilst the water contained in the front end is at liberty to escape at the waste pipe. In this situation the piston is moved towards the front end of the cylinder, and turning round the pinion and wheel K, (*figs. 1* and *2.*) moves both carriages in one direction: now by turning the cock N a quarter of a revolution in either direction, the same passages make a different communication, viz. from the entry to the front of the cylinder, and from the back to the waste; this throws the action upon the front side of the piston, drawing it to the back end of the cylinder, and moving the carriages in an opposite direction. By turning the cock only $\frac{1}{4}$ th instead of $\frac{1}{2}$ th, all the four passages are close stopped, and no motion takes place. The other cock, O, is more simple; thus, the entry is on one side, the pipe i at right angles to it, and the waste opposite the latter; the passage in the turning part of the cock is made diametrically through it, and another at right angles into it. In the position of the drawing, the pipe, i, is open to the waste, and permits the water in the cylinder 13 (*fig. 8.*) to escape; but when the cock is turned round one-fourth, to bring the short passage opposite the pipe i, a fresh supply of water will be admitted from the entry into the cylinder 13, or, by turning a little farther, all of them are shut. The cylinder marked 13 (*fig. 8.*) is fixed by screws in the middle of one of the cross bars D; it is accurately bored within, and fitted with a piston P, (see also *fig. 13.*) which is packed with leather cups, so that no leakage can take place by the side of it; in the upper side of the piston is a perforation for the reception of a steel pivot, which is fixed in the lower end of the great vertical spindle A, and thus supports its weight as it revolves; the upper end, a, of the great spindle is fitted through the centre of the cog-wheel, B, with a fillet, so that it has free liberty to rise and fall, but cannot turn round without the wheel; the wheel itself is supported by means of a cone formed on the lower part of it, and fitted into a socket supported at the top of four iron standards Q, Q, which are erected from the iron framing below, and thus they sustain the axis and wheel very firmly from the same frame as the rails F, F, which support the carriages. At the top of the vertical spindle a shackle, a, is fitted, by a pin with a head, inserted into the end of the axis, and retained by a cross pin; by this means the shackle is united to the spindle, to rise and fall with it, but not to revolve with it; a chain is attached to the shackle, and passes over a pulley, as shewn at m, in *fig. 2*, and thence to a small pulley n; to this is attached a larger wheel, o, from which a chain is carried, to suspend a heavy wooden ruler p, situated at some distance from the machine, and sliding in a groove; it has divisions shewing inches and parts graduated upon it, which are determined by an index fixed to the wood of the groove. On this scale, those divisions which are marked inches are three times that length, because the wheels n and o are as three to one in diameter:

meter :

PLANING MACHINE.

meter: this scale shews the thickness to which the machine will reduce the wood upon the carriages, the index being so adjusted that it stands at zero of the scale when the wheel 3 3 is lowered down till its cutter cuts the surface of the carriage; then by turning the cock N, the water is very gradually admitted into the cylinder 13, and elevates the piston P, the shaft, and wheel altogether, to any required height above the bench, which is shewn in inches and parts by the scale to very great accuracy; for by the cock being very partially opened, the wheel rises so slowly, that it can be adjusted to the greatest nicety. The wheels *n* and *o* are supported in the floor above the room, as is also the frame for the support of the axis, C, of the live and dead pulley *c*; the endless strap of this pulley is guided through an eye at the end of an iron rod *s*, *fig. 8*, which is joined to a lever T, coming down in reach of the attendant, who also manages the cocks N, O.

The construction of the cutters is shewn in *fig. 7*: here 3 is a section of a part of the rim of the wheel, and *t* an iron clamp screwed fast down upon it, as shewn in *fig. 3*; the clamp has a vertical mortise through it for the reception of the stem of the gouge cutter 7, which is fixed fast therein by a wedge piece and screw *v*: by this means they can all be adjusted till their edges come exactly into one plane, though not quite so deep as the faces of the planes: these are made, as shewn in *figs. 4* and *5*, in iron, being received into an opening in the rim of the wheel, and held fast by two bolts, *w, w*, with keys above the surface of the wheel to keep them fast; the plane iron, *x*, is double, and fixed into its place by an iron wedge *y*, formed similar to that of a carpenter's plane.

It only now remains for us to explain the construction of the dogs or claws for holding the work fast down upon the benches E, E; these are of two kinds, some fixed on the outsides of the carriage, and others in the middle, which draw up by screws to hold the wood fast; the carriage is composed of two large beams E, E, *fig. 9*, which is a cross section of it; these are united by proper cross pieces, and run upon the rails F, F, with metal pieces fixed on the lower sides of them. There are also several cast-iron frames fixed across, as shewn by the dark shaded parts *k*; each consists of two cheeks, all formed from one piece, and leaving a groove between them; in this groove a long screw, *l*, is fitted by a collar at one end, and operates upon a slider, 8, fitted into the groove; a dog marked *z*, and bent something like an S, is attached to this slider, and projects above the bench, having a sharp point which penetrates the wood 2 G, and forces it against the other claws, *r, r*, fixed on the outsides. When the wood, as G, *fig. 9*, is of small size, another small claw, 9, is applied; this is screwed into a nut of brass, which is fitted into the groove, then a second piece of wood, 2, is applied between it and the dog *z*, to transmit the force of the screw, *l*, to the other one at 9: the outside claws, *r*, are formed on the top of square stems, which are fitted through clamps affixed to the sides of the carriages, as shewn in *fig. 6*, and provided with clamp screws, by which they can be fixed at any required height. The dogs *z* are very simply attached to the nut 8, by being applied upon the flat top surface of it, and one point enters into a small hole made in the fore part of the nut 8; by this means it is simply hooked into its place, and when the screw is turned, it cannot get loose; another advantage is, that the clamp may be reversed, or turned the other way, and then the screw can be employed to hold the wood between *z*, and the claws, *r*, of the opposite side of the carriage. By these means the bench will hold a large piece of wood of the full width of the bench, or by introducing one of the clamps, 9, between each piece, it will hold as many narrow ones as will make

up the width, and they will be all planed together to one surface.

The endless chain H, which gives motion to the carriages, is connected with them by means of a piece of wood H, *fig. 9*, projecting down from it, and divided into two halves, between which the chain can be clamped or jambed fast when they are drawn together by a screw 6; therefore, by relieving this screw, the two halves open so much, as to permit the chain to slide freely between them; in this case the carriage will stand still. This expedient is used when it is required to have one carriage disengaged, for, in general, both are used together, in the following manner; suppose both carriages at the ends of their respective rails, the wood is laid upon them, and by the screw 6, which is turned with a winch, it is clamped fast on the chain. If the wood is winding, or irregular, it is made up at first by wedges, till its upper surface is parallel to the bench, and it is then fixed by the screws *l*; the carriages are then engaged with the chain, by turning the handle of the screw 6, which for that purpose comes to the outside. Next the cock O is turned one way or the other, to raise or lower the cutter, till the gauge, *p*, shews it to be at the thickness the stuff is to be planed to. All being thus prepared, the handle of the lever, T, is drawn; this draws the strap upon the live pulley *c*, and puts the machine in motion, and having acquired its full velocity, the same person turns the other cock N, and gently opens it; this puts the carriages in motion, and he can, by regulating the handle of the cock, give it any velocity he wishes; he can bring it up very quick, till the work comes under the cutters, and then move it very slowly, if much wood is to be reduced, or quicker when but little is to be taken off. In this manner the planing is performed from one end of the piece to the other, and the successive strokes of the cutters and planes follow each other so closely, as to leave an even surface, and with only such very slight scores across it, that the least shaving of a smoothing plane afterwards finishes it, from the roughest and most irregular timber which can be found.

In 1803, Mr. Bevans obtained a patent for a machine which we have seen at work for planing (or *slicking*, as the joiners term it) all kinds of mouldings or rebates, and ploughing grooves, as well as forming flat surfaces of small breadth, which it does with very little labour: in this machine, these operations are performed by the planes commonly used for similar purposes, with only such alterations as are necessary to adapt them to the machinery by which they are put in motion with mechanical power instead of human labour; they are to be used either singly, or combined together in any number, according to the width of the boards to be worked at once, and the nature of the work to be done, so as to plane up at one operation such moulding as joiners work up by using several planes successively for the different parts; this is effected by a kind of frame or box, which admits of fixing any number of planes in it, side by side, and at any distance asunder, to form the compound moulding required. The work is fixed fast on a bench, and the box of planes is made to pass over it, in the direction of its length, by a connecting rod communicating at one end with the box or frame containing the planes, and at the other end with machinery capable of affording a reciprocating motion.

This machinery consists of a crank, whose radius must be nearly half the length of the required stroke, and must be regulated accordingly: this regulation is effected by the arm of the crank passing through a mortise in a strong box, fixed on an axis, and sliding in the said box to any required length, where it must be fixed by strong screws, the axis being turned by manual exertion, by horses, steam, water, or any

other power, and having its motion regulated by a fly-wheel.

The planes are loaded, to keep them in contact with their work, by a long beam of wood, set up on end upon the sides of the box, and connected therewith by being divided into two cheeks, which at the lower sides are formed to an arc of a circle, and united to the box by chains, in the same manner as the beams of steam-engines are connected with their piston-rods. The upper part of the beam is made to pass always through one point by sliding between friction-wheels, or otherwise in a tube hung on two pivots perpendicularly over the centre of the work, and at such heights as may be most convenient for the length of the stroke required: the connecting-rod from the crank before mentioned is jointed to the upright beam, near its lower end, and by this means the motion is given to the box of planes, the chains and arches at the bottom allowing it in all positions to preserve the plane horizontal. To guide the box of planes in a rectilinear motion, and also to bear them off when they have been reduced to the depth required, fences are used, which are irons sliding perpendicularly in tubes or sockets in the box or frame, and clipping a tongue, or ruler fixed in the direction of the required stroke, in the frame supporting the bench.

PLANISPHERE, a projection of the sphere, and the several circles thereof, on a plane; as upon paper, or the like.

In this sense, maps of the heavens and the earth, in which are exhibited the meridians, and other circles of the sphere, are called planispheres. See PROJECTION.

PLANISPHERE is sometimes also considered as an astronomical instrument, used in observing the motions of the heavenly bodies; consisting of a projection of the celestial sphere upon a plane, representing the stars, constellations, &c. in their proper situations, distances, &c. Such is the astrolabe, which is a common name for all such projections.

In all planispheres, the eye is supposed to be a point viewing all the circles of the sphere, and referring them to a plane on which the sphere is as it were flattened. This plane is called the *plane of the projection*.

A perspective plane is only a plane of projection placed between the eye and the object, so as to contain all the points which the several rays drawn from the object to the eye impress thereon. But in planispheres or astrolabes, the plane of the projection is placed beyond the object, which is the sphere. The plane of the projection is always one of the circles of the sphere.

Among the infinite number of planispheres which the different planes of projection, and the different positions of the eye, would furnish, there are two or three that have been preferred to the rest. Such are that of Ptolemy, where the plane of projection is parallel to the equator; that of Gemma Frisius, where the plane of projection is the colure, or solstitial meridian, and the eye the pole of the meridian; that of John de Royas, a Spaniard, whose plane of projection is a meridian, and the eye placed in the axis of that meridian, at an infinite distance. This last is called the analemma.

The common defect of all these projections is, that they distort and alter the figure of the constellations, so that it is not easy to compare them with the heavens; and that the degrees in some places are so small, that they afford no room for operation.

All these faults M. de la Hire has provided against in a new projection, or planisphere; where it is proposed the eye shall be so placed, as that the divisions of the circles projected shall be sensibly equal in every part of the in-

strument. The plane of his projection is that of a meridian.

PLANISPHERE, *Nautical*. See NAUTICAL.

PLANITZ, in *Geography*, a town of Saxony, in the circle of Erzgebirg; three miles S. of Zwickau.

PLANK, a general name for all timber, excepting fir, which is from one inch and a half to four inches thick: if of less dimensions it is called *board*.

PLANK, *Garboard*. See GARBOARD.

PLANK-Hook, is a pole with an iron-hook at its end, with which the navigators shift their runs or wheeling-planks, as occasion requires.

PLANK-Piling, the same with *Camp-sheeting*; which see.

PLANK-Sheers, or *Plan-Sheers*, the pieces of plank wrought horizontally over the heads of the timbers of the fore-castle, quarter-deck, and round-house, for the purpose of covering the top of the side; hence sometimes called *covering-boards*.

PLANKENBERG, in *Geography*, a town of Austria; four miles S.S.W. of Talla.

PLANKENSTEIN, a town of the duchy of Stiria; four miles S. of Windisch Weifritz.

PLANKENWARD, a town of the duchy of Stiria; eight miles W. of Gratz.

PLANKING, in *Ship Building*, covering the timbers of a ship with plank; sometimes quaintly called *skinning*.

PLANO-Concave Glass, or *Lens*. See LENS.

PLANO-Convex Glass, or *Lens*. See LENS.

PLANSCHWITZ, in *Geography*, a town of Saxony, in the Vogtland; three miles W. of Oelsnitz.

PLANT, in *Botany*, *Gardening*, &c. See PLANTS.

PLANT, *Burning thorny*, a species of *Euphorbia*; which see.

PLANT, *Egg*, a species of *Solanum*; which see.

PLANT, *Ice*. See MESEMBRYANTHEMUM.

PLANT, *Parasitical*. See PARASITE.

PLANT, *Sensitive*, is the English name of a distinct genus of plants, called by botanists *Mimosa*; which see.

PLANT, *Bastard sensitive*. See ÆSCHYNOMENE.

PLANT, *To*, in *Military Language*, is to place or fix, as, *e. g.* to plant a standard. It likewise signifies to arrange different pieces of ordnance for the purpose of doing execution against the enemy or his works; as, *e. g.* to plant a battery.

PLANTA, in *Anatomy*, the lowest part, or sole of the foot of a man, comprehended between the tarsus and the toes.

PLANTAGENET, in *History*, an addition, or surname, borne by many of our ancient kings.

The term plantagenet has given infinite perplexity to the critics and antiquaries, who could never settle its origin and etymology.

It is allowed that it first belonged to the house of Anjou, and was brought to the throne of England by Henry II. where his male posterity preserved it till the time of Henry VII., a space of above four hundred years.

It is disputed, who it was that first bore the name. Most of our English authors conclude, that our Henry II. inherited it from his father Geoffrey V., earl of Anjou, son of Fulk V., king of Jerusalem, who died in 1144. This Geoffrey they will have the first of the name; and our Henry II. the issue of Geoffrey, by Maud, only daughter of Henry I. the second.

Yet Mahege will not allow Geoffrey to have borne the name; and adds, that, in effect, the old annalist of Anjou, J. Bourdigne, never calls him so. The first, Mahege adds, to whom he gives the appellation, is Geoffrey, third son of this Geoffrey V.

Yet must the name be much more ancient than either of these princes, if what Skinner says of its origin and etymology

logy be true. That author tells us, that the house of Anjou derived the name from a prince thereof, who, having killed his brother to enjoy his principality, took to repentance, and made a voyage to the Holy Land to expiate his crime; disciplining himself every night with a rod made of the plant genêt, genista, broom; whence he became nicknamed *Planta-genêt*.

Now it is certain that our Geoffrey made the tour of Jerusalem; but then he did not kill his brother, nor did he go thither out of penance, but to assist king Amauris his brother. Who then should this prince of the house of Anjou be? Was it Fulk IV? It is true he dispossessed his elder brother Geoffrey, and put him in prison; but he did not kill him; nay, Bourdigne observes, he was even released from the same prison by his son Geoffrey V., already mentioned.

Farther; this Fulk did make a journey to Jerusalem; and that, too, partly out of a penitential view: we are assured, by Bourdigne, he did it out of apprehension of the judgments of God, and eternal damnation, for the great effusion of Christian blood in the many mortal battles he had been in. The annalist also adds, that he made a second voyage; but it was to return God thanks for his mercies, &c.; to which we may add, that Fulk was never called Plantagenet; so that what Skinner advances appears to be a fable.

There is another common opinion, which appears no better founded; and it is this: that the name Plantagenet was common to all the princes of the house of Anjou after Geoffrey V., whereas, in fact, the name was only given to a few, and that, as it should seem, to distinguish them from the rest. Thus Bourdigne never applies it to any but the third son of Geoffrey V. and distinguishes him, by this appellation, from the other princes of the same family. Though it is certain that it was likewise given to the elder brother, Henry of England, as before observed.

PLANTAGINELLA, in *Botany*, is Vaillant's name for the *Limofella*; see that article.

PLANTAGINES, the second order of Jussieu's seventh class, for the characters of which class see **NYCTAGINES**. The *Plantagines*, or *Plantagineæ*, as Jussieu now terms them, in which he is followed by Mr. Brown, Prodr. Nov. Holl. v. 1. 423, are thus defined.

Calyx mostly in four deep segments. *Tube* petal-like, contracted at the summit, and generally four-cleft, resembling a *corolla*, but withering and not deciduous, inferior. (This "tube" is the Linnæan *corolla*.) *Stamens* four; their filaments long, prominent, inserted into the bottom of the "tube." *Germen* solitary; *style* one; *stigma* simple. *Capsule* divided circularly, of one or two cells, with one or more seeds in each cell. *Perisperm* (or *albumen*) none. *Plants* herbaceous. *Sexes* sometimes in distinct individuals.

Jussieu's genera of this order are *Pfyllium*, *Plantago*, and *Littorella*. The two first are combined by Linnæus, as well as by Decandolle and Brown. The latter author describes an albumen of the shape of the seed, and of a densely fleshy texture. He remarks that the analogy between the supposed *corolla* of the *Plantagineæ* and the membranous tube, which connects the *stamens*, in the neighbouring order of *Amaranthaceæ*, or *Amaranthi*, is weakened by the presence of the same part in the female flower of *Littorella*, a monoecious genus. We would observe however, though by no means inclined to invalidate the opinion of the part in question being a real *corolla*, that barren filaments are often found in female flowers, and therefore any other organ relating to the *stamens*, may likewise be present in such,

while the *stamens* themselves are absent. See **LITTORELLA** and **PLANTAGO**.

PLANTAGO, the herb Plantain, seems most probably to have been so named in ancient times, either from its resemblance to the sole of the foot, *planta*, in flatness, breadth, and lines or furrows; or from the depressed trodden appearance of some of the most common species, particularly *P. media*. Such is nearly the explanation of Ambrosinus, Ray, and the lexicographers. Linnæus, in Phil. Bot. 167, has "*Plantago, planta tangenda*." "A bold etymology," says De Theis, who, nevertheless, leaves as he finds this derivation, without searching further. Linn. Gen. 57. Schreb. 77. Willd. Sp. Pl. v. 1. 641. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 182. Prodr. Fl. Græc. Sibth. v. 1. 99. Brown. Prodr. Nov. Holl. v. 1. 424. Pursh v. 1. 98. Ait. Hort. Kew. v. 1. 250. Juss. Tourn. t. 48. Lamarck Illustr. t. 85. Gærtner. t. 51. (*Coronopus*; Tourn. t. 49. *Pfyllium*; Tourn. t. 49. Juss. 90.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Plantagineæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in four deep erect segments, short, permanent. *Cor.* of one petal, membranous, permanent, withering; tube swelling in the middle; limb depressed, in four deep, ovate, acute segments. *Stam.* Filaments four, capillary, erect, extremely long, inserted into the tube, alternate with the segments of the limb; *Brown*; anthers rather oblong, mostly beaked or crested, incumbent. *Pist.* Germen superior, ovate; style thread-shaped, half the length of the stamens, stigma simple, acute. *Peric.* Capsule ovate, somewhat membranous, of two or four cells, bursting by a transverse circular fissure, the partition at length becoming unconnected. *Seeds* several, oblong, convex on one side, concave on the other.

Obs. In some species the calyx is equal, in others unequal. Mr. Brown remarks that *P. Coronopus* has four cells to the capsule, with one seed in each cell. Gærtner, without mentioning the number of cells, says there are four seeds in each cell, in that species. Tournefort made *Coronopus* a distinct genus, merely on account of the deep segments of the foliage. It is rather to be wished that *Pfyllium* of authors could have been retained, as there are several species of that supposed genus, and their branched leafy habit is very different from what is usual in *Plantago*. Jussieu thought to distinguish *Pfyllium* by having solitary seeds, but the same is the case with many indubitable species of *Plantago*, as *P. Bellardi*, *cretica*, *media*, and others. For the difficulties attending the true nature of the *corolla*, see **PLANTAGINES**.

Ess. Ch. Calyx four-cleft. Corolla four-cleft, inferior, membranous; its limb reflexed. Stamens very long. Capsule with two cells, bursting all round.

The fourteenth edition of Linn. Syst. Veg. enumerates twenty-four species of *Plantago*; Willdenow has thirty-three, to which one is to be added from the Prodr. Fl. Græc., four from Mr. Brown's Prodr. Nov. Holl., and five from Mr. Pursh's American Flora. The genus is divided into two very unequal sections, of each of which we shall give some examples, particularly mentioning the five British species. The new ones all belong to the first section.

SECT. 1. *Stem* none. *Flower-stalks* naked. Thirty-six species in all.

P. major. Greater Plantain. Linn. Sp. Pl. 163. Willd. n. 1. Curt. Lond. fasc. 2. t. 11. Engl. Bot. t. 1558. Fl. Dan. t. 461. Camer. Epit. 261. (*P. media*; Matth. Valgr. v. 1. 435. *P. latifolia*; Ger. Em. 419.)—Leaves ovate, smoothish, somewhat toothed, with longish footstalks. Stalk round. Flowers imbricated. Seeds numerous.

PLANTAGO.

merous.—Common every where throughout Europe, as well as in North America, flowering at almost all seasons, in mild weather. *Root* perennial, of many long fibres. *Leaves* radical, several, upright or spreading, on channelled ribbed *footstalks*, ovate, broad, toothed or waved, nearly smooth, with seven or nine longitudinal ribs. *Stalks* several, erect, longer than the leaves, each bearing a dense cylindrical *spike*, of innumerable crowded, small, whitish *flowers*, with purple *anthers*. *Stigma* downy. *Capsule* elliptical, small, each cell containing several *seeds*, which are the food of small birds, and are often given to those kept in cages. This species is subject to many varieties, one of which we suspect to be *P. crassa*, Willd. n. 2.

P. asiatica, Linn. Sp. Pl. 163, has the appearance of *major*, but is more slender, with scattered *flowers* and angular *stalks*.—*P. maxima*, Willd. n. 3. Jacq. Ic. Rar. t. 26, is intermediate between the foregoing and the following.

P. media. Hoary Plantain. Linn. Sp. Pl. 163. Willd. n. 5. Curt. Lond. fasc. 4. t. 14. Engl. Bot. t. 1559. Fl. Dan. t. 581. Camer. Epit. 262. (*P. major*; Matth. Valgr. v. 1. 436. *P. incana*; Ger. Em. 419.)—Leaves ovate, downy, depressed, with very short *footstalks*. *Stalk* round. *Spike* cylindrical. *Seeds* solitary.—Common on open hills and pastures, where the soil is chalky or gravelly, flowering throughout summer. The broad depressed *leaves* are very conspicuous, and considered as a great blemish by those who are curious about their grass-plats. A single drop of oil of vitriol on the crown of each root is said to prove the best and most certain mode of destroying these intruders. The *spikes* are much thicker and shorter than those of *major*. The white *corolla*, pink *stamens*, and yellow *anthers*, make a far from inelegant appearance.

P. lanceolata. Ribwort Plantain. Linn. Sp. Pl. 164. Curt. Lond. fasc. 2. t. 10. Engl. Bot. t. 507. Mart. Rust. t. 67. (*P. longa*; Matth. Valgr. v. 1. 437. *P. quinquerteria*; Ger. Em. 422.)—Leaves lanceolate, entire, acute at each end. *Spike* ovate. *Stalk* angular.—Extremely frequent throughout Europe, in pastures and waste ground, flowering in summer. The more elongated, erect, narrower, greener *leaves*, with three or five ribs, and the short *spike*, the *calyx* of whose *flowers* is black, *corolla* brownish, and *anthers* white, mark the plant sufficiently. The entire *leaves* afford a less ambiguous specific distinction than the naked *spike*, by which Linneus meant to discriminate between this and *P. Lagopus*; for the *lanceolata* has a bracteated, though not a hairy *spike*, while *Lagopus* has a hairy one without *bracteas*.

P. Lagopus. Hare's foot Plantain. Linn. Sp. Pl. 165. Willd. n. 10. Ait. n. 10. Sm. Fl. Græc. Sibth. t. 144.—Leaves lanceolate, five-ribbed, distantly toothed. *Spike* ovate, hairy. *Stalk* round, clothed with upright hairs.—Native of the south of Europe, in dry open places; very common in Greece and the Archipelago.—*Root* perennial. Habit and size like the last, but the leaves are distinguished by their neat, prominent, more or less distant teeth. The *spikes* are shorter, rounder, hairy and pale. *Anthers* more obtuse.

P. albicans. Woolly Plantain. Linn. Sp. Pl. 165. Willd. n. 13. Ait. n. 12. Sm. Fl. Græc. Sibth. t. 145. (*Holosteum salamanticum*; Ger. Em. 423.)—Leaves lanceolate, oblique, waved, villous. *Spike* cylindrical, rather lax. *Stalk* round, longer than the leaves.—Native of Spain, the south of France, the Peloponnesus, and some of the Greek islands, but not common. It is perennial, flowering in summer. The divided leafy crown of the *root* sometimes

assumes the appearance of short stems. The *leaves* are long and narrow, spreading in an arched manner, not depressed; their surface glaucous, besprinkled with fine soft hairs. *Stalks* very hairy, especially when they first spring forth. *Spikes* long and slender, the *flowers* rather distant. *Bracteas* and *calyx* green, edged with white, hairy at the back. *Corolla* brown. *Stamens* red. *Anthers* yellow, with a small sharp beak. *Style* hairy.

P. alpina. Alpine Plantain. Linn. Sp. Pl. 165. Willd. n. 15. Ait. n. 14. Jacq. Hort. Vind. v. 2. 58. t. 125.—Leaves linear, flat. *Stalk* round, hairy. *Spike* oblong, erect.—Native of the Alps of Switzerland and Austria. Dr. Sibthorp found it about the summit of the Bithynian Olympus. The *root* is perennial. *Leaves* long and narrow, with taper points; the edges often fringed. *Stalks* hairy. *Spike* rather cylindrical than ovate. *Anthers* yellow, with a blunt beak. *Style* hairy. The Plantain noirâtre of Reynier, an alpine plant, with a short ovate dark *spike*, often mistaken for this, seems rather, as professor Schrader has hinted to us, a variety of *lanceolata*.

P. Bellardi. Bellardian Plantain. Allion. Pedem. v. 1. 82. t. 85. f. 3. Willd. n. 16. Ait. n. 15. Sm. Fl. Græc. Sibth. t. 146. (*Holosteum*, five *Leontopodium creticum* alterum; Ger. Em. 424.)—Leaves linear-lanceolate, hairy, flat. *Stalk* round, villous. *Spike* cylindrical. *Bracteas* pointed.—Found in Spain, Italy, Barbary, and on the summit of the Bithynian Olympus, as soon as it is clear of snow. The *root* is annual, erroneously marked perennial in Prodr. Fl. Græc. *Leaves* numerous, spreading, either quite entire, or toothed near the point. *Stalks* rigid, erect or ascending, two or three inches long, numerous, clothed with horizontal hairs. *Spike* thick, hairy, with prominent pointed *bracteas*. *Corolla* tawny, taper-pointed. *Anthers* yellow, with a pale two-lobed crest as large as their cells.

P. cretica. Cretan Plantain. Linn. Sp. Pl. 165. Willd. n. 17. Ait. n. 16. Sm. Fl. Græc. Sibth. t. 147. (*Holosteum*, five *Leontopodium creticum*; Ger. Em. 424.)—Leaves linear, flat, hairy. *Stalk* woolly, very short. Head of flowers roundish, drooping.—Native of Crete and Cyprus. A small annual species, remarkable for its numerous, short, deflexed, very hairy *stalks*. The *flowers* form a head, not a spike. The *corolla* is yellow, with a purple eye, its segments broader and shorter than in the last. *Anthers* similar to *P. Bellardi*, except that their crest appears to consist of one lobe only.

P. maritima. Sea Plantain. Linn. Sp. Pl. 165. Willd. n. 19. Ait. n. 17. Pursh n. 10. Sm. Fl. Græc. Sibth. t. 148. Engl. Bot. t. 175. (*Coronopus*; Ger. Em. 425. *C. sylvestris*; Matth. Valgr. v. 1. 449. *P. marina*; Ger. Em. 423.)—Leaves linear, channelled, nearly entire. *Spike* cylindrical, close. *Stalk* round, longer than the leaves.—Native of muddy sea-shores in Europe and North America, as well as of mountain rocks.—*Root* long, perennial. *Herb* extremely various in size and luxuriance. *Leaves* copious, spreading, linear, channelled, dark green, rather fleshy, occasionally hairy; their margins either quite entire, or sometimes beset with a few irregular teeth. On mountains they are generally narrowest and most entire. *Flower-stalks* few, ascending, about twice as long as the foliage, rather hairy. *Spike* slender, of numerous crowded or imbricated *flowers*. *Corolla* whitish. *Anthers* with a little sharp beak. *Style* downy. The structure of the *flowers* most agrees with *P. albicans*. The ripe *fruit* we have never examined. This species being, like the Thrift, *Statice Armeria*, found on the loftiest mountains, as well as on the sea-shore, its small alpine varieties have been taken for

alpina,

PLANTAGO.

alpina, or confounded with *subulata*, neither of which are really known to be natives of Britain.

P. subulata. Awl-leaved Plantain. Linn. Sp. Pl. 166. Willd. n. 20. Ait. n. 18. (*Serpentina omnium minima*; Lob. Ic. 439. f. 2. *Coronopus five Serpentina minima*; Ger. Em. 426.)—Leaves awl-shaped, triangular, striated, rough-edged. Stalk round.—Native of the Swiss alps and the Bithynian Olympus, as well as of the coasts of the Mediterranean. Gerard might have it in his garden, but we have never seen a garden specimen of this species. Its root is perennial, running down in one great cylindrical body to the depth of a foot, or more, and divided at the crown into many short-leafy tufts. The leaves are very copious, from one to three inches long, readily known by their narrow, linear, acute, triangular form, and rough edges. Flower-stalks rather stout, hairy, not numerous. Spikes cylindrical, not always perfectly close, various in length, and number of flowers, which seem to resemble those of *P. maritima*, but we have not been able to investigate their anthers. The bractees are hairy, as long, or longer, than the calyx.

P. gentianoides. Gentian-leaved Plantain. Prodr. Fl. Græc. n. 355.—Very smooth. Leaves ovate, three-ribbed, somewhat waved. Stalk round. Bractees ovate, naked, shorter than the calyx.—Gathered by Dr. Sibthorp on mount Olympus, with the preceding. Root perennial, thick. Leaves very like *Gentiana acaulis*. Stalks three or four inches high, quite smooth and naked. Spike cylindrical, slender, scarcely an inch long, perfectly smooth in every part. Bractees, as well as the calyx, obtuse and pointless.

P. varia. Variable New-Holland Plantain. Brown n. 1.—Hairy. Leaves lanceolate, three-ribbed, toothed; woolly, as well as the stalks, at the bottom. Spike many-flowered.—Native of various parts of New Holland without the tropic. Brown. It was sent us from Port Jackson, in 1793, by Dr. White. The leaves are three or four inches long, from half an inch to an inch wide, most tapering towards the base, or footstalk, which last is variable in length; both sides are clothed with dense short pubescence, and marked with three, occasionally five, longitudinal ribs; margin often beset with distant, very large and dilated, almost ovate, teeth, sometimes with obsolete ones, or none at all. Flower-stalks taller than the leaves, at least when full-grown, hairy, round, woolly at the base. Spike cylindrical, hairy, of rather numerous, but sometimes distant, flowers. Bractees ovate, concave, rather smaller than the calyx. Segments of the corolla rounded, or broad-ovate. Style nearly smooth. This species seems in many points akin to *albicans*, and to *Serraria* and its allies, but very distinct, as a species, from all of them.

P. debilis. Weak New-Holland Plantain. Br. n. 2.—Leaves lanceolate, toothed or entire, three-ribbed, flaccid; beardless, as well as the thread-shaped flower-stalk, at the base. Lower flowers of the spike scattered.—Found by Mr. Brown at Port Jackson, New South Wales. Nearly akin to the foregoing.

P. hispida. Hairy New-Holland Plantain. Br. n. 3.—“Hairy and hoary. Leaves linear-lanceolate, toothed; beardless, as well as the flower-stalk, at their base. Spike of many imbricated flowers.”—Native of the south coast of New Holland. Br.

P. carnosa. Fleshy New-Holland Plantain. Br. n. 4.—“Very smooth. Leaves lanceolate, deeply toothed, somewhat fleshy; naked, as well as the flower-stalk, at their base. Flowers from one to three.”—Native of the island of Van Diemen. Br.

P. Serraria. Saw-leaved Plantain. Linn. Sp. Pl. 166. Willd. n. 23. Ait. n. 20. (*P. apula laciniata bulbosa*; Column. Ecpfr. v. 1. 258. t. 259. *P. angustifolia ferrata hispanica*; Barrel. Ic. t. 749.)—Leaves lanceolate, five-ribbed, with awl-shaped tooth-like ferratures. Stalk round. Spike elongated, slender, cylindrical, imbricated. Bractees taper-pointed.—Native of Italy, Barbary, Zante, and various parts of the Mediterranean and Archipelago. Root perennial, thick, so as to assume a bulbous aspect. Leaves numerous, acute, hairy, distinguished by their long, parallel, almost pectinate, teeth, in which they essentially differ from the broad rounded imbricated teeth of *P. macrorrhiza* of Vahl, Willd. n. 22. The spikes also are very much longer and more slender than those of that species, composed of innumerable crowded flowers, and longish taper-pointed bractees.

P. Coronopus. Buck’s-horn Plantain. Linn. Sp. Pl. 166. Willd. n. 24. Ait. n. 21. Fl. Dan. t. 272. Engl. Bot. t. 892. (*Coronopus*; Matth. Valgr. v. 1. 448. *Cornu cervinum*; Ger. Em. 427.)—Leaves linear, in many pinnate segments. Stalk round. Anthers with a lanceolate crest. Capsule of four cells. Common in gravelly soils, and on sandy sea-shores, throughout Europe. It is annual, flowering with us all summer long, and conspicuous for its depressed pinnatifid leaves, spreading, close to the ground, in a star-like form, whence originated one of its names, Star of the Earth. Some of the starved maritime varieties have more fleshy, and nearly undivided, leaves. Spikes various in length, pale. Bractees pointed. Anthers tipped with a lanceolate membrane, or crest, akin to what is seen in *P. cretica*, Willd. n. 17. Style long, very hairy.

P. Cornuti, Jacq. Misc. v. 2. 351. Ic. Rar. t. 27. Willd. n. 26. Ait. n. 23, appears to us but a luxuriant variety of the last; its stamens indeed are shorter, and style rather longer; but there is hardly a distinct specific character to be discerned. It is pity that Jacquin did not examine the cells of the capsule. He merely says “fructus congenerum,” which conveys nothing, in this case, that we want to know. If he had specified that the part in question agreed with all the rest of the genus, except *Coronopus*, it would have been decisive.

P. Loeflingii. Narrow Annual Plantain. Linn. Sp. Pl. 166. Willd. n. 25. Ait. n. 22. Jacq. Hort. Vind. v. 2. t. 126.—Leaves linear, with slender distant teeth. Stalk round. Spike ovate. Bractees obtuse, with an orbicular membranous border.—Native of hills, and the borders of fields, in Spain and the south of France. No species is more distinct, or has been more mistaken, owing to Hudson and Linnæus having referred to this the toothed variety of *P. maritima*, figured in Pctiver’s English Herbal, t. 4. f. 9, and Ger. Em. 423. The root of *P. Loeflingii* is small, tapering and annual. Plant extremely variable in luxuriance. Leaves upright or spreading, linear, acute, very narrow, beset with fine, distant, taper teeth. Stalks spreading, thread-shaped, hairy, usually shorter than the foliage. Spike of few flowers, ovate, or almost capitate. Bractees orbicular, concave, pointless, formed of a broad membrane, with a thick green keel. The anthers seem to have a membranous tip, but we have not seen them fresh, and Jacquin’s figure has no dissected or magnified parts. He describes the capsule very accurately, of two cells, with one seed in each.

SECT. 2. *With a leafy stem*. Seven reputed species.

P. amplexicaulis, the first of these, Cavan. Ic. t. 125, appears a very doubtful species, perhaps allied to *albicans*, and certainly not more truly caulescent than some appearances of that plant. It is perhaps *P. angustifolia lanuginosa in-*

PLANTAGO.

cana, Barrel. Ic. t. 750; a specimen of which, from the south of France, we have referred to *albicans*.

P. Pfyllum. Flea-bane Plantain. Linn. Sp. Pl. 167. Willd. n. 28. Ait. n. 25. Sm. Fl. Græc. Sibth. t. 149. Ehrh. Pl. Off. 271. — Stem branched, herbaceous. Leaves somewhat toothed, recurved. Heads leafless. Bractæas uniform, lanceolate, obtuse. — Native of cultivated fields, vineyards, &c. in the south of Europe, very common in Greece, being doubtless the real $\psi\alpha\lambda\lambda\omicron\upsilon\varsigma$ of Dioscorides. The root is annual. Stem round, downy, glutinous, leafy; if slightly branched, erect; if much subdivided, decumbent. Leaves opposite, sessile, an inch or inch and half long, spreading, rather curved downward, linear-lanceolate, narrow, acute, flat, rough; tapering and entire at the base; sparingly but strongly toothed upwards. Flower-stalks axillary, solitary, round, rough, about the length of the leaves. Heads ovate, solitary, of several crowded flowers. Bractæas ovato-lanceolate, concave, blunt, rough at the keel, all uniform, and nearly of equal size. Calyx about as long as the bractæas, rough, obtuse. Corolla pale brownish-yellow, with pointed segments. Anthers with a short membranous point. Style hairy. Capsule obtuse, compressed, its circular fissure near the base. Seeds solitary in each cell. *P. Pfyllum*, Bulliard t. 363, in its large leafy bractæas and entire leaves, agrees best with *indica* of Linnæus.

P. Cynops. Shrubby Plantain. Linn. Sp. Pl. 167. Willd. n. 32. Ait. n. 29. (*Pfyllum majus supinum*; Bauh. Hist. v. 3. 513. Pl. fempervirens; Ger. Em. 587. Pl. alterum; Matth. Valgr. v. 2. 414.) — Stem branched, shrubby. Leaves entire, thread-shaped, straight. Bractæas orbicular, with linear points, much longer than the flowers. — Native of Provence, Italy, Switzerland and Bithynia. The stem is shrubby, and certainly perennial in our gardens, or rather greenhouses. Branches and heads purplish; the latter distinguished by their rounded membranous-edged bractæas, with linear rough points.

The cuts of old authors, given for the true *Pfyllum*, as Ger. Em. 587. f. 1. Matth. Valgr. v. 2. 413, and the modern plate of Bulliard, t. 363, having large bractæas under the heads of flowers, bear some resemblance to *P. Cynops*, but better agree with the *indica*, Linn. Sp. Pl. 167, and are possibly, like that, but varieties of *Pfyllum*. The *afra*, Linn. Sp. Pl. 168, appears to us much more clearly a luxuriant, biennial, and somewhat shrubby, variety of *Pfyllum*, with which it precisely agrees in every thing, but the more stout and shrubby habit of the stem.

P. squarrosa. Leafy-spiked Plantain. Willd. n. 29. Ait. n. 26. (*P. ægyptiaca*; Jacq. Ic. Rar. t. 28.) — Stem herbaceous, branched, diffuse. Leaves linear, entire. Heads oblong. Bractæas leafy, elongated, rough. — Native of Egypt. This is a very distinct annual species, whose long recurved bractæas are rough to the edge, scarcely at all membranous. The style is rough, much longer and thicker, and perhaps more perfect, in some flowers than in others.

PLANTAGO Lancolata, ribwort plantain or ribgrass, in Agriculture, has a perennial root, which, when old, appears as if bitten off at the end. The leaves are all from the root, truly lanceolate, distinguished by five (sometimes three or seven) prominent ribs, pointed, entire, or sometimes having a few teeth near the base. According to Withering, in maritime situations they are toothed all along the edges. They are of a dark green, mostly hairy beneath, taper at the base into a long flat footstalk, ribbed like the leaf itself, and at their insertion are invested with long white woolly hair springing from the crown of the root. The scapes or flowering-stalks upright, longer than the leaves, from

among which they spring; they are clothed at the base with the same kind of hair, and upwards are smoothish, round, with five deep furrows, slightly twisted, and terminated by a short ovate spike, imbricated with black scales, and enlivened with the prominent cream-coloured anthers, in its more advanced state. A spike will sometimes contain one hundred and thirty small flowers crowded close together, with an ovate pointed scale or bractæa at the base of each. The capsule contains two oblong shining seeds, of an amber colour, in each cell. The stalks continue to grow after the flowering is over, and sometimes shoot out to the length of two feet more. When it grows in meadows, the leaves are erect and drawn up: but in a dry barren soil they are shorter, broader, and more spread on the ground. It grows spontaneously in dry pastures and other places, where it is often left untouched by cattle, to feed small birds with the copious produce of its seeds. It has often been considered as a weed, occupying the room of grasses, and other useful herbs; but has lately been introduced into culture as a good food for sheep, or to be made into hay for cattle in general. Haller has attributed the richness of the milk in the alpine dairies, in some measure, to this plant. And it has been remarked by Linnæus, that it has been eaten by horses, sheep, and goats, but that cows refuse it. Sheep, however, will eat it either green or dried, provided it be well gotten; but it does not answer for pasturage, without a mixture of clover or grasses, according to some cultivators. Withering suggests that the total absence of this plant, in marshy lands, is a certain criterion of their wretched quality. In proportion as such soils are improved by draining, it will flourish and abound. But others have suggested, that in this climate the produce of this plant is not a criterion of excellence in soil, but merely of its dryness. But though botanists do not speak favourably of this plant as a pasture or meadow herb, practical farmers hold it in a degree of esteem. And it has been asserted by Mr. Zappa of Milan, that it grows spontaneously in every meadow of Lombardy, especially in those which are irrigated; that it vegetates early, flowers at the beginning of May, ripens in five weeks, and is cut with the *poa trivialis*; that the height of the leaves is about one foot, and of the stalk a foot and a half; that it multiplies itself much by the seed and a little by the roots, which it continues for some time to reproduce; that it is eaten heartily by every sort of cattle, and in particular by the cows in grass, and the cows like it most in May, having great influence on the milk; that the hay is eaten more voraciously by cows, and has on them great influence in the flesh; in short, that it is one of the best plants either for the milk or the flesh. Where kept well fed down by stock, there can be no doubt of its being a good and nourishing plant for both cattle and sheep stock.

And Mr. Young states, that he had long before recommended this plant for laying land to grass, and sowed it on his own farm. At the same time he thinks it extravagant to propose dandelion and sorrel as plants proper for a cow pasture; and conjectures that those plants being found among good ones, have qualities given them which do not properly belong to them; he is likewise inclined to make the same conjecture in respect to narrow-leaved plantain, ribwort, or rib-grass, and should even have preferred dandelion and sorrel to it: but he is cautious of opposing theory to practice. But Dr. Anderson contends that narrow-leaved plantain or rib-grass is well liked by horses and cattle, and yields a very good crop upon rich ground tending to dampness, if it is at the same time soft and spongy; but that upon any soil which has a tendency to bind, or upon dry ground

ground, it furnishes a very scanty crop. And it has been made use of in some parts of Yorkshire as a summer grafs. As an article of pasturage for cattle and sheep, it is there in high esteem; it is not, however, well eaten by horses; and as an article of hay it is held to be detrimental to the crop; retaining its sap an unusual length of time; and when fully dry falls into a small compass, or is broken into fragments, and left behind in the field. One advantage of this plant is, that its seeds may be easily procured genuine. A small proportion of it may be eligible: it has now stood the test of twenty years established practice, and seems to be still in good estimation even among farmers that are the most attentive in grafs husbandry. It has been stated by Mr. Marshall that he made a trial of it in Norfolk, as a substitute for clover, but gained no credit from the experiment: on which it has been observed that the fact is, horses do not affect it, and they are the principal consumers of the clover crop in that county. It is a plant that varies much in size as well as in the breadth of the leaves, &c. The narrow leaves have only three ribs. The spike is sometimes surrounded by large leaves, instead of the usual small bractæas: it sometimes becomes an abortive panicle: and it is found with two or three heads. Its qualities seem to be nearly the same with those of the following; and it is more used than that by the common people in some places.

It is probable that the sort which has been termed grafs-leaved plantain (*tenuifolia*) by Dr. Anderson, is only a variety of this. See RIB GRASS.

PLANTAGO, *Major*, the great plantain. This affords more seeds than the former, and is perennial. The root when old is the thickness of the thumb, præmorse or stumped, laying strong hold of the earth by its fibres, which strike deeply, and are whitish. The leaves petioled, seven-ribbed, or sometimes nine-ribbed, smooth, but somewhat hairy when young, about a hand in length, often remotely toothed about the edge. The petioles long, convex on the under side, concave above, each forming a kind of sheath at its base. The scapes upright, pubescent, longer than the leaves. The spikes cylindrical, very long, linear, composed of many closely imbricate flowers, under each of which is a lanceolate concave bractæa. This is likewise a plant, according to Mr. Zappa, that may be useful as a cattle food. It grows not only along the roads, near dung-hills, in damp and fat places, but in irrigated meadows also of every district in Lombardy, though more near the borders than in the centre of them; it vegetates later than the above, flowering towards the end of May; the leaf is six inches long, and the stalk almost a foot high; notwithstanding it is not tender, every sort of cattle like it, and cows are as fond of it as of the above sort. It has also been noticed by Mr. Curtis that cattle in general appear very ready to eat the leaves. Sheep, goats, and swine, also eat it well. But it is not in so much esteem among the farmers as the narrow-leaved sort. See RIB GRASS.

PLANTAGO, in the *Materia Medica*. The leaves of the plantago major, common great plantain, or weybread, have a weak herbaceous smell, and an austere bitterish subsaline taste, and their qualities are said to be refrigerant, attenuating, subtyptic, and diuretic. Plantago was formerly reckoned among the most efficacious of vulnerary herbs; and by the peasants the leaves are now commonly applied to fresh wounds, and cutaneous sores. Inwardly they have been used in phthical complaints, spitting of blood, and in various fluxes, both alvine and hæmorrhagic. The seeds, however, seem to be better adapted to relieve

pulmonary diseases than the leaves, as they are extremely mucilaginous. The roots have also been recommended for the cure of certain intermittents, and from the experience of Bergius, not undeservedly. An ounce or two of the expressed juice, or the like quantity of a strong infusion of plantain, may be given for a dose; in agues the dose should be double this quantity, and taken at the commencement of the fit. Plantain has been alleged to be a cure for the bite of the rattle-snake; but for this there is probably little foundation, although it is one of the principal ingredients in the remedy of the Negro Cæsar, for the discovery of which he received a considerable reward from the assembly of South Carolina. Woodv. Med. Bot.

PLANTARIS, in *Anatomy*, a small muscle situated in the calf of the leg. See GASTROCNEMIUS.

PLANTATION, in the *Islands and Continent of America*, a spot of ground which some planter, or person arrived in a new colony, cultivates and tills for his own use.

Plantations, or colonies in distant countries, are either such where the lands are claimed by right of occupancy only, by finding them desert and uncultivated, and peopling them from the mother country; or where, when already cultivated, they have been either gained by conquest, or ceded to us by treaties. See COLONY.

But there is a difference between these two species of colonies, with respect to the laws by which they are bound. For it hath been held (Salk. 411. 666.) that if the uninhabited country be discovered and planted by English subjects, all the English laws then in being, which are the birth-right of every subject, are immediately there in force. But this must be understood with very many and very great restrictions. Such colonists carry with them only so much of the English law as is applicable to their own situation, and the condition of an infant colony; such, for instance, as the general rules of inheritance, and of protection from personal injuries. But in conquered or ceded countries, that have already laws of their own, the king may indeed alter and change those laws; but, till he actually does change them, the ancient laws of the country remain, unless such as are against the law of God, as in the case of an infidel country. 7 Rep. 17. Calvin's case. Show. Parl. cap. 31. See CHARTER-Governments.

PLANTATIONS and *Trade*, *Board of*. See BOARD.

PLANTATION, in *Gardening*, a certain collection of different kinds of trees or shrubs, which are cultivated either in nursery grounds or other places, in order to be raised and protected to proper and suitable states of growth for being afterwards planted out in particular situations; or which are planted out for ornamental or other purposes, generally in the way of beautifying portions of ground or particular spots surrounding or lying about country residences, &c. The former are commonly denominated nursery plantations,

As most plantations of the latter sort, besides the ornament

PLANTATION.

ment which they give, afford considerable improvement to the places where they are formed, they should, of course, be more fully attended to and regarded, in all cases and situations wherever there is any sort of want or deficiency of either variety or beauty. This is still further desirable, as they have also an excellent effect in all such situations, by giving an idea of grandeur to them, and at the same time an air of cultivation and fertility.

In the forming of these, as well as other kinds of plantations, it is constantly necessary to select and provide the plants with a view to the nature of the soils, and the peculiarity of the exposures in which they are to be placed.

The plants, for the most part, after being first raised from the seeds, or by some other proper means, and having a little growth, are transplanted or removed into nursery grounds or plantations, where they remain for two, three, or more years, according to their different natures, and the uses for which they are intended; when they are, in general, ready, and in the best order for being planted out in different sorts of plantations, as larger plants are commonly found not to succeed so well. Larger plants may, however, be occasionally found necessary, especially in particular cases of ornamental planting, and for producing blinds, covers, and shades, in some peculiar situations; but for all common purposes, in almost all cases of this sort of work, young plants, which have been raised in, and procured from, the nursery plantations, and which are from about two or three to five or six feet in their growth, are mostly in the best and most proper states to be employed, and especially in all situations where timber is in any way an object. The plants should also be chosen as nearly of equal growth as possible for the same plantation.

For all ordinary purposes of planting, a small portion of ground will be quite sufficient for raising the young plants; but in all nursery grounds of any extent, there are mostly pretty large tracts set apart for the purpose of receiving plantations of these kinds, where a great many different sorts of trees and shrubs of various growths are kept, being set out in rows at different distances, according to their ages and other circumstances. See NURSERY.

The young plants in all these nursery plantations should be kept clean and free from every sort of obstruction, by digging or hoeing frequently between the different rows, until they become of sufficient growth for being set out in other situations.

In regard to the preparation of the ground before the making of the plantations, in all those of the nursery kind it is constantly dug or trenched over with the spade; and this is likewise sometimes the case in forming those of the ornamental or other descriptions; though frequently the plants are put in without, simply by digging separate holes at suitable distances for the reception of each; or by forming slits or crevices for them by the point of the spade. The more fully, however, the land can be prepared previously to the plants being introduced, the better they will commonly succeed. Plantations are also occasionally raised by sowing the seeds of the different sorts of plants, either in small drills, or over the whole surface of the ground, after being made ready in the above manner, or without undergoing any such preparation, but in the latter case the plants seldom thrive so well.

In preparing the land for nursery plantations, a little manure is not unfrequently had recourse to in digging it over; but for those other kinds this is very rarely necessary.

In making all these sorts of plantations, the most proper times for performing the business is in mild dry periods, either in the autumnal, or very early spring seasons.

In the forming of every sort of plantation where any kind of ornament is intended, as great a variety as possible of different sorts of hardy trees and shrubs should constantly be had recourse to, such as those of the middling and more tall growths of both the kinds, which in the former or those of the tree sorts are usually the oak, elm, ash, beech, chestnut, hornbeam, birch, alder, maple, yew, larch, willow, hazel, &c.; and in the latter, or shrubby sort, the pine, fir, cedar of Lebanon, holly, bay, laurel, yew, ever-green oak, box-tree, and some others. See DECIDUOUS, EVER-GREEN, and FOREST Trees.

In regard to the general disposition of the plants, the deciduous and ever-green kinds may be planted in separate compartments, or in mixture, and sometimes the tree kinds by themselves, some in running varying plantations, towards the boundaries of lawns, parks, paddocks, &c., others in avenues, groves, thickets, and clumps, variously disposed in different parts; and sometimes the trees and shrubs together, forming shrubberies, wildernesses, shady walks, and wood-works; placing those of taller growth backward, and the lower in front; bordering the whole with the most beautiful flowering shrubs and showy ever-greens, especially next the principal walks and lawns, varying the form of all the several compartments, sometimes by moderate sweeps and curves outward and inward, of different dimensions, other parts in long easy bends, varied projections and breaks, so as to diversify the scene in imitation of natural plantations. The proper distances, in planting, may be from five or ten to fifteen or twenty feet: for example, the tall trees designed for continued plantations may be from ten to fifteen or twenty feet, varying the distance in different parts, according to light and shade, &c.; and those in groves, where open, may be fifteen or twenty feet distance, and where close ten or twelve; for thickets, five or six feet, or closer in particular places where a very dark shade or thick coverture of wood is required; and in clumps of trees, from five or ten to twenty feet between the trees in each clump, varying the distance occasionally, according to growth, as also the sorts and numbers of trees in each, from two or three, to five, ten, or more. The form of the clumps may sometimes be triangular, at other times quadrangular, pentangular, &c., and some in curves, others in straight lines, to cause the greater variety. And in shrubbery clumps, and wilderness compartments, where the trees and shrubs are employed promiscuously, they may be planted from five to ten feet distance; the taller growths being placed backward eight or ten feet asunder, placing the lower plants gradually forward according to their gradations, to the lowest in front, as above, at four or five feet distance: and if the trees and shrubs of the plantations in general are disposed somewhat in the quincunx way, they appear to the greater advantage, and produce a better effect in some instances.

Before the making of any of these sorts of plantations, the grounds should, in all cases, be well inclosed in some manner or other, and the plants be afterwards kept properly cleaned, pruned, and thinned out, so as to take their full growths.

Mr. Loudon, in his Treatise on Country Residences, after noticing the great variety which exists in trees, shrubs, and all sorts of wood, both in respect to beauty and utility, remarks, that all ornamental plantations may be divided into two kinds; namely, those whose grandeur is the effect to be produced, and those whose variety or beauty is the principal object. And it is asserted, that as grandeur depends more upon the whole than upon the parts, it may be produced where only one kind of tree is employed or made use of;

but

PLANTATION.

but that as variety depends upon the parts alone, many different kinds are necessary. This, it is contended, has given rise to a most erroneous opinion and very pernicious practice among landscape gardeners and planters. Imagining that variety is produced by mixture, their rule is to mix as many kinds together as they possibly can, and never to let two trees of the same species be seen at once. This is said to be their recipe for variety in plantations; which they follow, as far as possible, in every arrangement of vegetables, from the parterre to the forest. But instead of affording variety, it is maintained that it, on the contrary, produces the most distracting incongruity. The eye, in examining the parts, finds no connection—no harmony—no relief—no repose of effect—no difference of composition, or change of character; or, if the surface of such a plantation be looked upon from a distance, it is on account of the indiscriminate mixture of forms, more dull and monotonous than if only one species of tree had been used. Its outline against the sky is a mere unvaried zig-zag line; which, except in artificial plantations, is not to be found in the whole range of nature. It is further supposed, that this mixture is evidently produced by their ignorance of that which constitutes variety; for it does not, as they imagine, consist in the diversity of separate parts, but “in the diversity of their effects when combined together; in a difference of composition and character:” very different from the other is the effect of such a variety; it relieves the eye and interests the mind, without fatiguing either.

Therefore, in forming a plantation with a view to variety, instead of selecting such trees and shrubs as are of opposite character, those differing in the slightest degree are in general much better adapted to the purpose. The upright spiry form of the larch, mixes very ill with the round head of the oak. But by choosing trees of intermediate forms, and placing them in the interval between these extremes, a natural connection and gradation will be produced. By this means, with the store of trees and shrubs which we possess, an endless source of variety in woody scenery may be had from the forms of trees and their modes of growth, independently of any other material of landscape.

But there is another source of variety which arises from grouping, or the manner in which trees are disposed, more than from the number of distinct species. And this is chiefly applicable to extensive plantations where the general character is grandeur, as woods, groves, and forests. It is produced by mixing together tall and low growths; planting irregularly, sometimes very close, at other times very wide; by pruning so as to expose trunks, stems, or branches, in some places, and to conceal them in others, &c. Much of the effect also depends on the diversity of age in the low growths, as well as the difference of magnitude and accidental form of the trees. This kind of variety, it is supposed, exists in the greatest perfection in natural forests; and the true way to study its principles is, to observe in them the effects of time, accident, the browsing of cattle, the felling of timber, and other circumstances. By this means we shall, it is imagined, be enabled to transfer the same effects, sometimes by different and sometimes by similar methods, to artificial plantations. Natural forests cannot be too strongly recommended to the examination of the ornamental planter. Almost every other operation of planting is mechanical; it is in this mode of grouping, and following the principles of nature, that the man of taste will be distinguished from the mere gardener. The effect of putting in practice the principles to be derived from such a study may be seen, it is said, in Mr. Price's

woods at Foxley, which no man of taste ever, it is supposed, saw without being filled with wonder and delight.

A still further source of variety, which is independent of the modes of growth or the manner of disposition, is in the colour. Therefore, in order to assist in the arrangement of a numerous collection of trees and shrubs, a knowledge of the harmony of tints is essentially necessary to the planter, and of very considerable importance to his success in the business.

It may be thought, that the different tints of green in trees are distinctions too minute to be attended to for this purpose; but reflection and experience shew that they are of material consequence in this sort of scenery. Imagine, says the writer, two woods of equal and considerable extent,—the one composed of the yellow green of the weeping willow, the other of the dark green of the oak: how different must be the impression received from each, though the general form and composition of both, at a distance, would appear in some measure the same! It is evident, that the effect of the different greens must be much more conspicuous in scenes intended to be more minutely examined by the eye: how different even the green of the gooseberry-bush and currant-tree when opposed to each other!

It is remarked, that the tints of trees may be considered in respect to their harmony with one another—with external scenery—their gradation—and their particular effects. The harmony of tints is supposed, in general, to be derived from the respective agreement, disagreement, and destruction of particular kinds when mixed together; and that these harmonies, discords, and privations, will remain true, although the colours should not be bright. The slightest tinge will have the effect. When weak colours that agree are placed near each other, they support and give spirit to one another. A hawthorn hedge, among the green of pasture fields, has, it is asserted, the same dull green appearance; but when opposed to the brown of a ploughed field, it appears with peculiar spirit and force. And again, the ploughed field, were it not contrasted with the hedge or some object of a similar colour, would appear dark and colourless; but opposed to the hedge, it appears of a rich brown. A Huntingdon willow, observed alone, it is maintained, appears green like any other tree; but, contrasted with an oak or a chestnut, it approaches to white; and the oak again, by the contrast, appears much darker than before. If plantations were arranged agreeably to these principles, the colours would, it is believed, at all times appear striking and forcible; but from the opposite conduct, that of mixing all colours together, they are annihilated, and their separate effects destroyed. In consequence of this, it is frequently said that *trees have no colour but green, except in autumn*, and that attention to these principles in their arrangement is frivolous. But nothing can shew greater ignorance of nature. Green is indeed the predominant colour of trees; but it is only in one or two of the summer months that it nearly absorbs every other colour. All trees have their peculiar autumn and spring tints, which in midsummer are only weakened, not destroyed; and, whether it be not of greater importance to attend to the harmony of these tints, than to neglect it altogether, because the effect would be in some degree lost during a month or six weeks in summer, every man of taste or sense is left to judge. It is evident, that the *harmony of wood with landscape* must depend upon the general principles that have been already mentioned. One principle of harmony is, that the general appearance of the wood planted about a mansion should correspond with the general appearance of the wood in the surrounding country:

PLANTATION.

if otherwise, the space so planted will appear a formal spot in the general view. The same principle requires also, that in a scene where water is a prominent part, and has a tendency to make the landscape too cold; trees of warm tints (by no means evergreens) should be principally planted adjoining to it. On the contrary, where buildings make the landscape too warm, cool tints, such as ever-greens, should be planted, to counteract that tendency. Some objects in landscape require to be relieved and set off with spirit, others require to be kept under, or prevented from becoming principal. These, and a great number of other important particulars, are effected by the colouring of trees and shrubs.

It is remarked, that if we operate with the permanent dark and light greens, as with light and shade in landscape painting, we may produce many of the effects of *aerial perspective*. The imaginary height of a hill may be increased, by placing dark coloured trees at the base, and lighter kinds towards the summit; so may the apparent breadth of a lake, by planting trees of a dark green on the side nearest the eye, and others of a lighter tinge on the opposite side; in the same manner, bays or recesses may be apparently deepened by placing the light coloured greens on the prominences. This mode of operating with the colours of trees will only be deemed unimportant, it is supposed, by the ignorant or unexperienced.

But though the harmony of tints only produces a pleasing scene, their disagreement, on the other hand, may produce a striking effect. An outline, which cannot be varied in form, may be broken by the opposition of its tints, or by masses of dark and light green. Two or three trees together, that form a striking contrast with all around, may attract the eye, and fix it so, as either to induce it to admire some object, as a building; or prevent it from viewing something disagreeable, or less noble, in the scene. Trees of a reddish tint, or ever-greens, have the power of attracting the eye in an astonishing degree; and in many places, where the former have been planted at random among other trees, they distract the whole scenery in the autumnal months.

In regard to the arrangement of the materials of plantations, the great business is that of uniting beauty with utility in the most natural manner, which is best accomplished by the consideration of forests or woody wastes, which are the species of scenery that approach as near or nearer to nature than any other in this country; by this means may be discovered the indications of every valuable or useful practice in beneficial or picturesque planting. But in respect to arrangement where utility alone is the main object, it may be observed, that as every tree has a certain soil and situation, or those in which it will prosper better than in any other, that is, produce timber in the greatest quantity and best quality, and as this tree will in general pay better than more valuable kinds which would not thrive, or would grow too quick in such places; it follows, that in the formation of useful plantations, one great object should be, to accommodate the trees to these circumstances, as already seen. And, as the properties of soils and situations are various, these naturally lead to a corresponding variation of the sorts of trees also; and this *variation*, it is supposed, *at once produces ornament and utility*. Thus, in natural forests such an arrangement actually takes place. Hence, in one part, the oak is found as the principal tree; the hazel the principal undergrowth; and other particular plants, grasses, and mosses, chiefly to prevail. While a little farther on, a few beeches mingle with the oaks; still more onward the beech becomes the principal tree; the undergrowths changing in

the same way, the thorn, with other plants, grasses, and mosses being found. Ultimately the land becomes moist, when the birch gradually shews itself, and this moisture increasing as the birch retires, it is succeeded by the alder; each with their appropriate undergrowths, or ever-varying glades of pasture, as shewn by Gilpin in his "Forest Scenery," and "Walks in a Forest," &c. In this manner the arrangement proceeds throughout the whole forest; and if the soil were minutely examined, it would be found to vary correspondently with the trees. Where the oak abounds, it will generally be deep and good; dry where the beech succeeds best; and moist in different degrees where the birch and alder prevail.

Planters, it is supposed, have seldom a sufficient idea of the effects and advantages that might be produced, by having recourse to this mode of arranging vegetables in artificial scenery, whether the first expense of planting, the future beauty, or the ultimate utility of it be regarded. Only those who combine a knowledge of botany with painting, it is imagined, can conceive the variety and perpetual interest that may be thus created in a place even of the smallest extent, and with the least natural advantages. In the present mode, all improved places have a sameness in their general appearance; as they are composed of the same kind of mixture. The shrubbery, or a part of it, in one place, is precisely the same with another at a distance from it, and affords a pattern of all others; but were nature followed in this respect, the variety would be endless. Nothing, it is believed, could then be more interesting, than to walk or ride through a place thus laid out; to view the trees, shrubs, plants, and even the grasses and ferns; the infinite diversity of shapes, colouring, and composition of the trees and shrubs; and the ever-varying openings and intricate recesses between them; again, varied with groups and turfs of flowering plants and ferns, spreading among the grass, in every direction; and all this independently of every other object, such as buildings, rocks, water, animals, distant prospect, and even variety in the grounds. So that by this mode of planting, a situation naturally the most dull and insipid, may be made infinitely varied and interesting. And it is asserted, that this mode of arrangement is not more beautiful in shrubberies, flower-gardens, and green-houses, than it is profitable in extensive plantations.

In the disposition of the wood in plantations about country residences, the forms of the surfaces the most desirable to be planted in the grounds, are chiefly to be determined by the character which they are to assume. Where they are of an even or level surface, there can be nothing to interfere with this rule; but when the surface is varied with swells, hollows, and abruptnesses, the great art is, to combine the natural character of the place with the character to be created; and when these are understood by the designer, the best effect will be produced. However, independently of artificial characters, nature always points out rising grounds for plantations. Wood placed on knolls or swells, it is contended, heightens their effects, and gives spirit, force, and intricacy to a scene, otherwise tame and monotonous. On the contrary, wood placed in the hollows only, or in the hollows and eminences indiscriminately, destroys all the expression or natural features of the surface, and often produces deformities. Nothing is more noble than a steep hill clothed with wood; but, imagine this hill perfectly bare, while the surrounding country is wooded, and it becomes a deformity in the general view. To plant the hollows, and leave bare the eminences, is, in almost every situation, counteracting nature. Even in pleasure grounds or parks, a
group

PLANTATION.

group of shrubs, or a few trees, placed upon a rise, however gentle, set off the scene, as it were, at once; but, plant them only in the low places, and they will remain until full grown before they have much effect; and at that time, though the residence may have the appearance of wood at a distance; yet, when it is examined particularly, the features of the grounds are totally destroyed. There are many places in the country which have a sufficient quantity of old wood, which, if it had been planted with a proper regard to the natural variety of the grounds, would have made them as superior to their present state, as that is now to such as are totally destitute of trees. It is not, however, meant that no low situation should be planted, or that trees should be placed formally on the summit of every eminence; on the contrary, dills, dingles, and such romantic places should be shaded with wood; and not a group, nor a single tree should exist, but what appears connected with other trees, as well as with the grounds. Taking the country in a general point of view, the hills should be wooded; the rising grounds between the hills and vallies diversified with handsome residences, pasture lands, and some corn fields; and the lowest parts kept in a state of almost perpetual aration. These vallies in general, in order to promote a more free circulation of air, and favour the particular mode of farming to which they are suited, should be free from plantations, and sometimes even from hedges. Viewed from rising grounds in the autumnal season, they should present broad flat shades of rich yellows, interspersed with farm houses, and relieved by roads, canals, or rivers. An example in illustration of which is supposed to be met with in the valley called the Carle of Gowrie in Scotland.

In fact, it is contended, that there is nothing of so great importance as the situation of wood, whether the general appearance of the country and the improvement of its climate, or the beauty and value of individual properties, are had in contemplation. All other operations that can be effected about residences, are thought comparatively of little consequence. It is the wood, it is supposed, like the shades in a picture, that gives the effect; and as it is by the situation and relative connection of these shades, that an expressive or unmeaning picture is produced by the painter; so by the site and connection of plantations, a place is either deformed or beautified by the planter. Even small groups and detached trees are of the utmost consequence in this respect, when skilfully performed or put in their places, but where the contrary is the case the whole is spoiled. It is said to be lamentable to see the plantations that are daily making at a considerable expence, without any regard to this principle. In this level country it may, however, be thought of less consequence, than where the grounds are strikingly varied by nature, as in Wales and Scotland, where it is of the first importance. It is conceived, that in less than half a century, wood may completely change the appearance of the residences of gentlemen, and of the whole country; and those who understand the subject will allow, that there is some danger of the change producing a bad effect, as is illustrated by the example of some parts of Scotland.

In respect to the quantity and disposition of the wood which is to surround residences, it should either, it is said, be arranged in groups, so close together, as, at a small distance, to appear a connected mass; or one or more large irregular masses must be planted, to which all the groups and single trees should seem to belong. The former method, it is suggested, will have a good effect when the surface is unvaried; but can only be adopted with propriety, when the situation of the residence is elevated or on a de-

clivity, where moisture or stagnation of air will not prove pernicious. But the latter method may be had recourse to in every case. In *levels*, the principal masses or masses may be placed at some distance from the house; which may still be connected with it or them by intervening groups judiciously placed for the purpose. On *irregular surfaces* and *hilly situations* the same mode may be successfully adopted. The masses may generally be placed upon the hills, while the connecting chain, thickets, and straggling groups descend into the valley, and embrace the house. These groups should never be large, three or four trees together will generally be sufficient; their effect depends not upon the magnitude of the group, but upon their number and apparent connection. This object is attained by making the groups loose and open, and by scattering single trees among them; and again by grouping these single trees, and even many of the groups and thickets, with low growths, as hollies, thorns, honeysuckles, ivy, &c. to take away from the formality of solitary and naked items rising from smooth turf. The common method of scattering single trees here and there, and always at some distance from one another, gives a formal *stemmy* appearance to a lawn or park, which is never seen in nature. An example of the valuable mode of forming plantations, which is here recommended, is given from Foxley.

In regard to the nature or kinds of plantations, they may be considered as the *grove*, which is a collection of trees without undergrowth; the *wood* or *forest*, which is a collection of trees with undergrowth; the *copse-wood*, which is undergrowth alone; the *group*, which is composed of two trees or more, or a tree and one or more shrubs planted together; and the *avenue*, which consists of single rows of trees set in different directions according to fancy or utility.

The first, or *grove*, is divided into two kinds, the former of which is commonly employed for ornament in parks and other similar places. These are mostly uninclosed; they admit the pasture to grow below them; and appear, in walking through them, as a large collection of single trees. The latter kind of which is composed of the pine or fir tribe. This sort is for the most part planted upon hills, moors, commons, or other places of the same nature; they are thicker than the former kind, and they effectually prevent the growth of pasture: they are principally inclosed. The character of the former is generally solemnity and beauty; that of the latter chiefly picturesqueness. Groves are originally planted equally thick with other plantations. As they grow, they are gradually thinned out, until the trees left standing are able to defend themselves from cattle. The fence is then removed or destroyed, the outline varied, and the spaces between the trees sown with grass-seeds. Fir groves are often allowed to remain, without thinning, until they are fifteen or twenty years old; and then they are considered as a full crop, and cut regularly over. See GROVE.

The second, or *wood*, is mostly well suited both for ornament and utility. It is primarily formed by planting timber trees at such distances as would form a grove, and filling up the interstices with the kinds intended for undergrowth. This, it is supposed, is the most generally applicable kind of plantation, and commonly the most profitable, particularly when in stripes and belts. There, the undergrowth thrives best; thickens the stripe below; completes the shelter; and by concealing the real breadth, gives a massiveness and grandeur to narrow plantations, which they can never have, if planted in the grove style. Oak undergrowth is generally the most proper, and, if its worth were fully known, many plantations might be made

PLANTATION.

made of double their present value, have a much better effect, and afford better shelter. Most plantations, especially in the northern parts of the country, though they generally go under the title of woods, are, in reality, of the grove kind. None of the trees are found kept under the rest in a decided manner, cut over, and allowed to spring up again, while a certain number, from fifteen to thirty feet distance, are preserved until their timber be full grown; but the trees being once planted, are allowed to grow up together, only a few being thinned out where they are too much crowded, and even this is very little attended to. Those removed are either cut over, or grubbed out by the roots, as is found most convenient, without any regard to propriety. In consequence of this management, a few bushes of undergrowth are found in some places, and the rest of the ground, if not shaded too much by the crowded trees, is covered with pasture; and neither the pasture, nor the undergrowth, from being intermixed, can be turned to the advantage of the proprietor. There are other plantations where undergrowth exists among timber trees in a more general way, but of kinds which are of little or no use, except for fuel; and this is by no means a profitable article, especially in a cold district. But, on the other hand, there are woods in some places where both timber and undergrowth are cultivated; and it is from observing the great profits derived by the proprietors of these, that the advantages of raising oak undergrowth in woods is so strongly recommended. The very high price which is given for oak-bark is generally known; and the sum given for an acre of oaks, from twelve to twenty-five years old, valuable for the bark alone, is very considerable. Instances of these kinds are adduced from the woods of Dunkeld in Scotland, where there are lands of very little value for any other purpose, that contain oak woods, chiefly of the natural kind, the undergrowth of which is sold every twenty-five years, at the rate of from 35*l.* to 60*l.* the acre, clear of all expences; or from 25*s.* to 48*s.* the acre annually; independent of the value of the timber trees left, fifty of which commonly remain to each acre. And in more low and sheltered situations, it is contended, that double the advantage would be derived, in consequence of the more quick growth, as in such cases the undergrowth would become equal in size in the course of twelve or thirteen years, and therefore afford two cuttings instead of one in the same length of time; besides more uniform crops be produced, from the greater regularity in planting, which would be adopted. But lest oak undergrowth should be thought to be made more profitable than it really is, it is further remarked, that, in the most cold, hilly situations of Scotland and Wales, it will afford upwards of 2*l.*, and in more favourable situations above 3*l.*, the statute acre annually; and if properly attended to in its early growth, still more. The easy and cheap method of raising it by means of the acorn, is also a great recommendation of it, as well as that of its growing better and more expeditiously in this way. Where an undergrowth alone of oak is wanted, other sorts of timber trees may be planted with the acorns. These statements strongly display the superiority and advantages of woods over other kinds of plantations; but the recommendation of the formation of them, exclusive of groves or coppices, is not by any means intended, as, on the contrary, there are thin kinds of land, with bad understrata, where the fir formed into groves, is more profitable than any other kind of plantations: and there are steep and rocky banks, where no tree can be so advantageously cultivated as the common ash; and rich moist places, where no plantation will turn out so profitable as oaks. But, ge-

nerally speaking, it may be safely asserted, that woods are the kind of plantation that ought to be most commonly formed; and that though the kind of *timber* grown in these woods must vary according to the consumption of different places, yet that oak will be found the best and most profitable *undergrowth* of any. See **WOOD**.

In respect to the third sort, or copse-wood, it is alone seldom desirable in point of character, though, in many places, it is the most profitable kind of plantation. Its formation is very simple: when of a proper size it is cut down; after which, the stools spring up again; and this operation is had recourse to in a periodical manner. These kinds of woods are, however, in general, under a very wretched sort of management in many parts of this country. See **COPPICE**.

With regard to the fourth, or group, whether made in the ground, or in the hedges which divide the fields, it should be well and ornamentally formed.

And in the fifth, or avenue, whether the rows of the trees be leading to a residence or in other parts of grounds, they should be well suited to the nature of their situations and other circumstances. See **AVENUE**.

In all cases where plantations are to be made, it is of great consequence to fix upon the most proper kinds. In ascertaining this, the kinds of woods and species of trees met with in the surrounding country, the market, the present or probable expence of carriage by land or water, and a variety of other circumstances, are to be considered; and that kind fixed upon which will in the end turn out the most profitable. And the plantations being once made, the particular kinds should be held strictly in view in their management afterwards. A collection of oaks designed for a grove, if not gradually thinned out as they grow up, will never, it is supposed, succeed; but if the same collection were intended for a wood, thinning them out, in place of cutting over, would lessen the crop of undergrowth. There is no method of management that will make a collection of firs a wood; nor can a collection of hazels, or other low growths erroneously planted to rear a grove, ever be made to assume that character. The idea of forming and preserving a distinct character in plantations, it is thought, is never sufficiently attended to by planters in general,—a certain space is to be planted; and it is filled up with trees at random. It is supposed to be from this neglect alone, independent of all others, as those of previously preparing the soil to planting, cultivating, and keeping it in order afterwards, training and thinning, with other operations, that few plantations yield one-third of the profit which they might. It is, however, suggested, that, if the particular kind of plantation to be formed, were previously determined upon, the business might proceed with a degree of certainty unknown and unpractised at the present period, as well as other great advantages be derived from it.

In relation to the outlines or boundaries of plantations, they should, it is imagined, be determined by the character which they are to assume. The tree being a picturesque object, all wood is consequently so; and as the addition of wood to ground is always an addition of picturesque qualities, although frequently blended with grandeur or beauty, hence the propriety of irregular or picturesque outlines in all kinds of plantations. Where the character to be produced is that of grandeur, the bounding line, it is asserted, should consist of bold angular prominences, succeeded by deep incisions, forming large bays and promontories; and to give these still greater effect, and vary their outline against the sky, they should be adapted to the variations of the ground, the bays being in the hollows, and the promontories

PLANTATION.

mentories on the eminences. In this mixture of curves and straight lines, the former should generally be obtuse and convex, and the latter of considerable length. All should appear "irregularly great." Such plantations as are made on hills ought always to assume the character of grandeur. Those introduced among cultivated fields, and bounded by straight lines, may also have a very grand effect, if due regard be had to vary their outline, by attending to the angular inflections of hedgerows, or belts of planting; though, in this case, it is impossible to avoid a degree of formality, which is always connected with cultivation, and which, being essential to it, cannot be considered as a deformity. But where a plantation is to be made of a size which does not assume the character of grandeur, the outline should be composed of such a mixture of straight and curved lines as will relieve each other, produce variety and intricacy, and correspond with the surface of the ground. Nothing can be more unnatural or insipid than a serpentine line, or one wholly composed of curves, as the boundary of a plantation: it is totally void of variety and intricacy, and destitute of force and spirit, which are some of the great objects gained by planting, and which it is the peculiar property of irregular or picturesque forms to confer. The outline, whose ornament is a principal consideration, should be broken by single trees and groups, so dispersed, as to increase its irregularity, and take away from that formality and sameness which lines of every kind have, when viewed alone. Those who attempt this, without understanding effect, clog up the bays and recesses, in place of making them appear deeper and more intricate; and thus they do much more harm than good. The outline is also greatly varied, and much improved, by mixing low growths with timber trees along the boundary of the plantation; and afterwards by taking away the fence, and making partial inroads or recesses of different forms and degrees of depth. In open groves, where the trees stand single, and have no fence, the outline is easily varied, and with great effect. The different forms, colours, and shades of green, when no other mode is applicable, may often have a surprising effect in apparently varying the boundary of a plantation; a fine example of which is seen at Keddlestone. Groups and thickets, when planted in place of a circular fence, like a clump, should always have the most irregular outline. This irregularity is apparently increased, by mixing low with tall growths at planting; by removing the fence, when these are grown to a certain height; and by judicious thinning. The great beauty of small groups and single trees arises from their connection, and the bends and inclinations of their stems. This may be produced, by planting two or more trees or shrubs in one hole, of different kinds, or the same kinds of different sizes, &c.; and connecting these by others straggling round them. And the most beautiful examples for this sort of work are, it is supposed, to be found in natural forests, or woody banks and commons, where trees have sprung up in an accidental manner. Examples representing the manner in which small masses and groups of trees may be grown, without giving a clump-like appearance to the inclosures, are given from the working plans of planting at Barnbarrow, and other places. The general forms of the masses may, it is asserted, be infinitely varied on a level surface; and on an irregular one, they should correspond with it. And, as it is believed that this principle is universally applicable, there never can be the smallest necessity or apology for any thing of the clump kind in such cases.

PLANTATION, in *Rural Economy*, a portion of land planted with timber, or other trees. It is plain that planta-

tions, when judiciously made, not only afford great improvement to estates, but are highly ornamental to the country. They should, therefore, be more particularly attended to, where there are large tracts of poor barren lands, that cannot be converted to the more profitable purposes of tillage or grafs. They have also a fine effect in the vicinity of habitations. And in many cases, the proprietors of estates, whether of large or moderate sizes, may reap great pleasure and advantage in allotting a part of them to this use, as they give an air of cultivation and fertility; and after eight or ten years, in many cases, bring in great profit by the gradual thinning of the underwood, besides leaving a sufficiency of standards to attain full growth. The expence attending the making of plantations, and the knowing that they must wait several years before the trees have made any considerable progress, or can afford any advantage, often, however, prove an obstacle in attempting the prosecution of the business. But the expence of planting, where the plants are raised on the grounds, will not be so great as may be imagined, especially as a small spot of nursery-ground will raise plants sufficient, in three or four years, to plant a great many acres of land; and the expence of raising and planting, with the loss of time in waiting till the plants attain some growth, will be compensated by the first fall or thinning, in eight or ten years after planting; and the stools which remain shoot up again, in many of the deciduous kind, and afford a lopping every eight or ten years, exclusively of the due portion of standards, left at proper distances to attain full growth for timber, or other purposes.

It may be noticed that, in former ages, this island abounded in natural plantations or forests, which spread themselves over the surface of it to a very considerable extent, and which were composed of various sorts of tall or lofty trees of great magnitude, all blended together in a promiscuous manner, and of spontaneous growth. Those vast forests were never planted by any human hands; such only have been employed for ages in cutting them down: for in many places there were such profusions of useless wood, that large tracts were obliged to be cleared by degrees, in order to cultivate the ground for other purposes; which, together with the necessary demands for the wood, from time to time, for building, and other uses, as well as that of the owners of such lands reaping considerable advantage from the sale of their timber, continued gradually, one generation after another, the practice of grubbing up and destroying their timber woods and plantations without measure: and but few ever planted any in the place of that which they cut down; so that, in many parts, there is at this time almost a general demolition of woodland, and many considerable estates have scarcely any timber of consequence or value left standing upon them. There is, in short, a want, in most places, of nearly a complete renovation of the timber; which should take place as soon as possible, otherwise the nation, in many parts, may sustain considerable injury, from the increasing scarcity of so important an article of internal produce and general consumption. Every portion of land in the kingdom, which is capable and proper for the purpose, ought, therefore, without delay, to be covered with plantations of this sort. All the different steep, waste, unproductive tracts of land, in different situations, are in general fit for being converted to this use, often with considerable advantage, as from two or three to eight or ten times that which they could be made to afford under any other system of cultivation. It is indeed remarked, that of such barren wastes, there are few spots which would not admit of being improved in this manner, under particular circumstances;

PLANTATION.

circumstances; and that there is a very great number of tracts, of vast extent, on which it would be far more profitable to the owner than that of attempting any other sorts of improvement; as in all those cases where the soil is dry, but of an infertile nature, of a heathy, stiff, hard, clayey quality, with little surface produce, or where it is much covered or filled with rocks and stones; that, in fact, there is hardly any land so poor, barren, rocky, or unproductive, as not to admit of it, when properly managed.

In making plantations, it is necessary to choose such trees as are adapted to the nature of the particular soil and situation. As to the proper sorts of trees, most of the deciduous and evergreen kinds may be employed with propriety; and young plants of from about two or three to five or ten feet in height always prove more successful than such as are older, as those of a younger growth always take root sooner, and establish themselves more firmly, so as to form considerably the finest plantations at last, and are of longest duration; for though large trees of from fifteen to twenty feet in height, especially of the deciduous kind, may with care be transplanted, so as to grow, and probably thrive tolerably well for some years; yet, by not rooting firmly, like young plants, they often fail, and, after some years standing, have hardly any shoots, and at last gradually dwindle and perish altogether.

In cases where large plantations are to be formed of forest and timber trees, particular sorts must be chosen, consisting of deciduous and evergreen trees. Of the first kinds, the oak, elm, ash, beech, chestnut, hornbeam, birch, alder, maple, sycamore, plane, poplar, lime, walnut, mountain ash, larch, willow, &c.

There are two methods practised in forming plantations: one is by raising the trees from seed at once, on the ground where the plantation is intended to be, especially the deciduous kinds, and which is effected by sowing the seed in drills, a yard asunder, the plants remaining where raised, thinning them gradually; the other method is by previously raising the plants in a nursery, till two or three feet high, then planting them out into the places allotted them. The former, or that of raising the plants where they are to remain, though it may be more expeditious, and at once gets quit of the trouble of transplanting, requires greater attention for a few years, till the plants have shot up out of the way of weeds; but the trees, from their always remaining where raised, without being disturbed by removal, may probably make a greater progress. The latter method, or that of raising the trees first in the nursery, is probably the most commonly practised, as being thought the least troublesome and expensive, with regard to the attendance at first to the young growth. In respect to the preparation of the ground for the final reception of the seed or plants, it is mostly performed by deep ploughing and harrowing upon such ground as the plough can be employed on; but where this or other tillage is not practicable, only young plants from the nursery can be used, digging holes, &c. at proper distances, one for the reception of each plant. Where, however, the ground can be tilled, it will prove very advantageous, by performing it a year before; sowing it with a crop of turnips, or other plants of a similar kind; and when these come off, ploughing and harrowing the ground again, for the reception of either the seed or plants the ensuing season. The most proper season for making this sort of plantation, either by seed or plants, is any time in dry mild weather, in the autumn, as from October till February, or later in moist soils. Where large tracts are to be planted, both the seed and plant methods must be pursued all winter, at every favourable opportunity. The ground, where the

plantations are made, should be previously fenced in all round with a deep ditch, to guard against the encroachments of cattle, or other animals. In respect to after-management, while the plantations are young, they must have some attendance to destroy weeds, which may be expeditiously executed by hoeing between the rows in dry weather, or occasionally by horse-hoeing: and this care will be needful for two or three years, especially to the seedling plantations, until the trees are advanced out of the reach of weeds; after which no farther trouble will be required, until the trees are ready for the first fall or thinning for poles, faggots, &c.

After eight or ten years growth, they are mostly of a proper size to begin the first fall by a moderate thinning, which will serve for poles and faggot-wood, to repay some of the expence of planting, &c. But only a part of the plantation should be lopped the first year; thinning out the weakest and most unpromising growth first, leaving a sufficiency of the most vigorous plants pretty close, to grow up for larger purposes; the year following thinning another part, and so continue an annual thinning fall, till the whole plantation has been gone over; cutting each fall down near the ground, leaving the stools to shoot out again, especially in the deciduous kinds; and by the time the last fall has been made, the first will have shot up, and be ready to be cut again. So the returns of the fallings may be contrived to be every six, seven, eight, or ten years, or more, according to the uses the poles or wood are wanted for: and if large poles, &c. are wanted, the fall may be only once in fourteen, eighteen, or twenty years; still at every fall being careful to leave enough of the most thriving plants for standards; being left pretty close at first, that they may mutually draw each other up in height, but thinned out in every succeeding fall as they increase in bulk, and so as to leave a sufficient quantity of the principal trees at proper distances, to grow up to timber; which in their turn, as they become fit for the purposes intended, may also be felled, according as there may be a demand for them, to the most advantage; having young ones from the stools coming up in proper succession, as substitutes, so as the ground may always be occupied as completely as possible in all parts.

In regard to the advantages that may be derived from the use of different sorts of trees in plantations, they have been stated as very considerable by different writers. In Mr. Mellish's experience, on a forest sandy soil of 3s. an acre value, as stated by Mr. Young in his Eastern Tour, in 1771, and made in different ways; as by cleaning the land in the manner as for grain, ploughing once and then setting the trees, by trench-ploughing and setting, and by not ploughing at all, but setting in holes, with the ground only cleared for them: the results were found nearly equal; but what superiority there was, was in favour of the ploughing method. The sorts of trees were Scotch and spruce firs, larch, oak, ash, chestnut, beech, birch, &c.; the whole being mixed. The Scotch and spruce firs have grown much the fastest, and generally succeeded with scarcely any failures. The number set on the acre mostly 5000; the expence of inclosing, raising the trees, and planting, 3*l.* the acre. In five years they require thinning, when the wood taken out about pays for the labour; the number thinned out being about a thousand. And in five years more they are thinned again, when another thousand trees are taken out, which make good hedge wood and hedge stakes; the value about five pounds more than pays the expence of the labour. When these thinnings have been performed, three thousand are left, which have been found from experience

PLANTATION.

to be then worth 6*d.* each on an average, as standards, and clear of all expences, if sold. At this time another thousand should be taken out. Two thousand are therefore left, which, at 30 years growth, will be worth, as they stand, 1*s.* each; and at 40 years, they will be worth 2*s.* each. This is the produce of such poor forest lands; but this experienced planter has, Mr. Young says, many Scotch firs planted 35 years ago in good land, which are worth 40*s.* each, and a great many from 25*s.* to 35*s.* On these *data*, Mr. Young calculates the profit of the plantations, at different periods, in this manner:

Account of an acre of firs at the end of the fifth year.

	£	s.	d.
First inclosing, raising, planting, fencing, &c.	3	0	0
Interest of the above sum five years	0	15	0
Rent 15 <i>s.</i>	0	15	0
	4	10	0

In five years more.

Reparation of the fences	0	5	0
Interest of 4 <i>l.</i> 10 <i>s.</i> for five years	1	2	6
Allow for compound interest	0	15	0
Rent	0	15	0
	2	17	6

First five

Expence at the end of ten years	7	7	6
Received for thinnings	5	0	0
	2	7	6

Excess

At the end of twenty years.

Rent	1	10	0
Reparation of fences	0	10	0
Interest	1	0	0
	3	0	0

Received for 1000 at 6 <i>d.</i>	25	0	0
Value of 2000 remaining, at same rate	50	0	0
	75	0	0

Deduct as above	£ 3	0	0
Excess at end of five years	2	7	6
	5	7	6

Clear profit in 20 years

Which is *per acre per annum*

And that supposing the 2000 trees left ten years longer, the account will stand thus:

	£	s.	d.
Received for 1000 at 6 <i>d.</i>	25	0	0

Clear profit in 40 years

Or *per acre per annum*

It is further stated, that this account of the expences, produce, and profit, of planting forest land at 3*s.* an acre, shews the amazing profit of such undertakings. Plantations have, in general, been raised with a view merely to beauty, or else through a very noble patriotic motive of being serviceable to the country; but it is evident, that they may be undertaken with very different views—with those of profit: so that a man may cut down the trees he planted himself, and expect to reap, in so doing, very considerable profit. If he cuts all down at the end of 20 years, and leaves not a single tree, he gains a profit clear of near 70*l.* an acre, which is 3*l.* 3*s.* *per acre per annum*, from the first planting. Let me ask the most skilful farmers of this country, how they will exceed such a profit, by any system of common husbandry, on such poor land? It before appeared, that common good husbandry, after some improvements, would yield but 1*l.* 1*s.* 11*d.* *per acre* profit; so that the planting to cut in 20 years, is more than thrice as beneficial, and certainly much less exposed to accidental losses. But supposing the trees left 30 years, in that case the thinnings pay,

PLANTATION.

for the first 20 years, 1*l.* per acre per annum; and at the end of the 30th, the account from the first planting is 3*l.* 17*s.* 1*d.* per acre; and in 40 years, 5*l.* 6*s.* 1*d.* After which time, they may be supposed to decline in quickness of growth, and consequently had better be cut down, in point of profit. It is noticed, that if beauty of situation is not, in some respects, commanded, we seldom see plantations of quick-growing trees; but it is evident, that poor soils should be planted upon in the mere view of profit. A crop of firs, instead of a crop of wheat, barley, or oats, at 20 years growth, which so many men may expect to see arriving at perfection, turns out far superior. One of the most profitable farms would be a 30 years lease of such land, with liberty to plant and cut down. One of 20 years, which is a shorter period than the generality of long leases, would, thus applied, exceed common husbandry on such soils.

It is added, that Mr. Mellish has a waste, inclosed with a ring fence of 700 acres, which he would let at 3*s.* an acre, tythe free. Suppose a person hired it under a lease of 30 years;

The raising, planting, &c. &c. would come to	£ 2100
Rent for 700 acres, for 30 years	3150
Reparation of fences, suppose	30
Interest of 2100 <i>l.</i> for 30 years, at 4 per cent.	2520
Total expence	7800
Produce.—Thinning in 10 years, at 5 <i>l.</i> an acre	3500
Ditto, in 20 years, 1000 per acre, at 6 <i>d.</i> , 25 <i>l.</i>	17500
Cut down at 30 years, 2000 per acre, at 1 <i>s.</i> , or } 100 <i>l.</i> per acre	70000
Total produce	91000
Total expences	7800
Clear profit	83200

This account is stated in the style of a common farm; the first expenditure called stock, and compound interest, not calculated. It is very evident that no man, possessed of such soils, who can hire them for 20 or 30 years, under a planting lease, need ever be distressed at the idea of younger children's fortunes, or raising large sums of money in future. A moderate expenditure will, by planting, secure the certain possession of any sum that may in future be wanted.

And in Mr. Bevor's experiments, as stated by the same writer, Scotch firs, in 18 years, are found to be worth 2*s.* 6*d.* And a whole plantation of 50 years growth, worth 50*s.* on an average: they stand 20 feet square, which is 108 to an acre. In another plantation on a moist sandy loam, larches of 18 years growth, are worth 3*s.* 6*d.*: spruce firs among them not half so good, which Mr. Bevor attributes to their being trimmed up; others on same soil and growth, not served so, are almost double the size.

Mr. Berney, at Bracon Ash, has also made great improvements by planting land of 20*s.* an acre. Oaks, of 50 years growth, are worth 15*s.* each: they stand 15 feet square; this is 180 on an acre. Larch, in 18 years (20 from the seed), are worth 6*s.* each: they grow out of underwoods that pay 20*s.* an acre. Some few of 20 years, worth 15*s.* each. Silver firs in the same wood not quite so large, but they beat both the spruce and Scotch. They all stand 15 feet square in the underwood. And in another plantation without underwood, Scotch firs, of 18 years, are worth 2*s.* 6*d.*

each: they stand 8 feet square; which is 680 on an acre, or 85*l.*; that is, 4*l.* 14*s.* per acre per annum, exclusive of thinnings. No husbandry, Mr. Young contends, will equal this. A man who would plant for profit must not regret land of 20*s.* an acre.

The Weymouth pines, in 18 years, much larger than Scotch firs of 22 years.

But in Mr. Fellowes' of Shottesham experiments, who has, according to Mr. Young, tried various trees, some years ago, so that he is now able clearly to judge which is the most profitable; the following are the results.

Experiment 1.—A plantation of Scotch firs of 45 years growth, 20 feet square, on land of 15*s.* an acre, are now worth 20*s.* each on an average. At that distance there are 108 trees on an acre, or 108*l.*; which is 2*l.* 9*s.* per acre per annum, from the first planting, exclusive of thinnings, which would more than double it. But the grafts under the trees would have let for many years past at 7*s.* an acre.

Experiment 2.—Another plantation of Scotch firs, 38 years growth, standing in rows 14 feet wide and 10 in the rows, are now worth 12*s.* on an average. This distance gives 300 on an acre; and at 12*s.* they come to 180*l.*, or 4*l.* 14*s.* per acre per annum, besides thinnings. The rent of the land 15*s.*; poor rates, 1*s.* 3*d.* per annum in the pound; and tythe, till 20 years old, 5*s.* an acre; the grafts under them now 5*s.* an acre. It is sufficiently evident, Mr. Young thinks, that no husbandry can equal this.

Experiment 3.—Chesnuts in 38 years, on the same land, standing 14 feet by 10, are worth 15*s.* each. This is 225*l.* per acre; or 5*l.* 16*s.* per acre per annum, besides thinnings.

Experiment 4.—Scotch firs in 38 years, on the same land, measure 17 feet of timber on an average, for which Mr. Fellowes has been offered 11*d.* a foot: that is, 15*s.* 7*d.* a tree. They stand 14 feet by 10. An acre would therefore be 233*l.* 15*s.*; or 6*l.* 3*s.* per acre per annum, besides thinnings. These trees are 60 feet high.

Experiment 5.—On the same land larch trees, of only 31 years growth, are as large as the firs of experiment No. 4, which shews that the larch is a much quicker grower. Spruce by them not so large as either. The pinafter of 38 years, larger than the Scotch. The cedar of Lebanon, of the same age, would now cut into planks 12 inches wide.

Experiment 6.—A very striking comparison between the larch and the spruce fir, was tried by planting an old gravel pit levelled, surrounded by a plantation of Scotch fir, with those two forts in alternate rows. The larch is from 6 to 12 feet high; whereas the spruce is but 2 feet on an average.

Experiment 7.—A large plantation of many acres of a poor gravelly land at 8*s.* an acre, containing Scotch and spruce firs and larches, is now 16 years old; they are in squares of ten feet, and are worth;

The Scotch, 2*s.* 6*d.* each.

The spruce, 3*s.* 6*d.*

The larches, 4*s.* 6*d.*

At ten feet, there are 435 trees on an acre.

The Scotch, at 2*s.* 6*d.* come to 54*l.* 7*s.* 6*d.*; or per acre per annum, 3*l.* 7*s.*

The spruce, at 3*s.* 6*d.* to 76*l.* 2*s.* 6*d.*; or per acre per annum, 4*l.* 15*s.*

The larch, at 4*s.* 6*d.* to 97*l.* 17*s.* 6*d.*; or per acre per annum, 6*l.* 2*s.*

All three exclusive of thinnings. Suppose, says Mr. Young, we calculate these at no more than paying the rent, tythe, and town charges; and that the larch, in 20 years, come only to 100*l.*, which is, however, under the truth: let any

PLANTATION.

any one calculate the profit of hiring land on a 21 (or more) years lease, and immediately planting. In what other application of the lands can such great profit be made, as gaining 6*l.* an acre without any risk, and almost without any expence? It is true such a conduct cannot, like the culture of corn and grafs, be general, for reasons obvious to every one; but as far as the whole demand of any neighbourhood extends, it is profitable to execute it.

And suppose, says he, 5 acres of larch planted every year; at the end of 16 or 17 years, 5 acres will every year be cut down, of the value of 500*l.*: from that day a regular product of 500*l.* a-year is gained from the application of 100 acres of land. Let to a tenant, these 100 acres produce 40*l.* a-year; but planted, they produce 500*l.* a-year. What an amazing difference! Or suppose a single acre planted every year, after the expiration of 18 or 20, to cut annually 100*l.* a-year from only 20 acres, which let, would yield but 8*l.* a-year. How beneficial a conduct!

Mr. Fellowes has also planted plane-trees, and finds them to thrive amazingly in low moist situations. They will, in such, grow much faster than the poplar. One he has of 30 years growth that will cut into planks 20 inches broad; but so vast a size he attributes in some measure to its standing on the edge of a ditch through which the drainings of a farmer's pigsties run. Poplars, in some parts of the kingdom, are planted in low situations, to the exclusion of every thing else: it is of consequence, therefore, to know that the plane will do better. But Mr. Fellowes, in general, recommends the larch as preferable to every other tree he has tried; and which will pay a planter much greater profit than any of the rest. These statements shew the great profits formerly derived from planting, and they have not been less since.

Mr. Davis, steward to the marquis of Bath, after observing that oaks and beeches planted on the best spots of ground, and nursed by Scotch firs, will not be so valuable at sixty years old, as the Scotch firs are on the very worst land at thirty, further states, that four firs will grow where one oak or beech will grow; for firs are the better, and deciduous trees the worse, for being crowded. And that a great deal of poor heathy shallow land, which will produce Scotch firs in the greatest perfection (and a great deal of the land planted by lord Bath is of that description), will not grow oak or beech at all, nor in fact any thing but Scotch fir.

Even larch has failed univerfally on all those spots where the upper stratum is peat. Having lately had occasion to cut some rides through some extensive plantations of Scotch firs which were planted just thirty years ago, I measured the land, and the trees which were cut off it, very exactly, and the following result shews that the profit of planting Scotch firs has been full seven *per cent.* compound interest; whereas no plantation of deciduous trees, within my knowledge, has paid five *per cent.* simple interest. Indeed we usually reckon, in valuing estates for sale, that the common growth, even of elm timber, on its most favourite soils, is seldom equal to more than three or three and a half *per cent.* simple interest.

336 Scotch firs, of 30 years old, cut upon a statute acre, average measure three feet *per tree*, valued at only 10*d.* *per foot, viz. 2s. 6d. per tree*, amount £. s. d.
to, *per acre*, - - - - - 42 0 0

At the time of planting, this land, then newly inclosed from a common, was not worth above 2*s. per acre per ann.*, which, at twenty-five years purchase for the fee simple, amounts to - 2 10 0

And the cost of the trees and planting was not above - - - 3 0 0

Total expence *per acre*, even supposing }
the land to be annihilated } 5 10 0

5*l.* 10*s.* principal will increase, in thirty years, as follows:

£. s. d.

At 5 *per cent.* simple interest, to only - - - 13 15 0
At 5 *per cent.* compound interest, to - - - 23 15 5
At 7 *per cent.* compound interest, to - - - 41 17 4

So that the Scotch firs, which have increased 5*l.* 10*s.* principal to 42*l.* in thirty years, have paid upwards of 7 *per cent.* compound interest. Transactions of the Society of Arts. &c. vol. xvi.

The statements which are given below, as drawn up by Mr. Mason, shew the great advantage of making plantations with ash, on the grounds of his grace the duke of Newcastle, together with a valuation of the lands previous to their being planted with the trees.

In this case, the expences of planting the hundred and eighty acres are said to have amounted to the sum of 2700*l.* for which his grace will have the additional rent of 300*l.* a-year.

The bishop of Landaff has made the following calculation of the probable profit of converting the waste rocky lands in Westmoreland into plantations with larch. A thousand acres of this sort of land might, he supposes, be inclosed with a circular wall six feet in height, (where the stones can be easily gotten, as they may in most parts,) after the rate of six shillings an acre, or 300*l.* for the whole; five hundred larches two feet in height, (so as to enable them to retit the long grass,) might be planted on each acre for fourteen shillings; hence a plantation of 500,000 larches might be made for 1000*l.* Now 1000*l.* improved at compound interest, at the rate of 4*l.* per cent., would, in 60 years, amount to the sum of 10,519*l.*: this is the accumulated loss attending the inclosing and planting 1000 acres of rocky land in sixty years. The rent of 1000 acres, at one penny per acre, is 4*l.* 3*s.* 4*d.* a-year; in eight years the larches would be out of all danger from sheep, so that the loss of rent ought only to be estimated for eight years; but 4*l.* 3*s.* 4*d.* a-year, though improved after the same rate of compound interest, would not amount to 40*l.* in eight years; say, however, that it would amount to 81*l.*, which is allowing more than two-pence an acre for the annual rent of the land, then would the whole expence attending the plantation in 60 years be 10,600*l.* If the amount of 81*l.* for 52 years be taken into consideration, the expence of the plantation in 60 years will be 11,222*l.* He has here supposed sheep to be shut out of the plantation for eight years; if it should be found that sheep will not crop

the larch, (and from more than one observation he has reason to believe that they will not,) they need not be shut out at all; nor, on districts where nothing but sheep are depastured, need any fence be made. He knows the advocates for close planting, instead of 500, would require 5000 larches for each acre; he is not convinced of the utility of such close planting, except when it is intended to nurse up oaks, or other kinds of wood; but if that mode should be adopted, the thinnings, after twenty years growth, would pay the expence of it. At the expiration of 60 years, suppose that only 250 larches remained on each acre, or that one-half had perished, the probable value of them may be thus estimated. From a great many experiments made by himself and collected from others, he finds the annual increase in circumference of the larch at six feet from the ground, to be an inch and a half on an average of several years; and this inference has been drawn from the actual admeasurement of larches in different parts of England and Scotland, and of different ages, from ten years old to fifty. On this supposition, the larches would measure, one with another, ninety inches in circumference, at six feet from the ground: A larch which measures ninety inches at six feet from the ground, would measure above seventy at twenty feet from the ground; but supposing seventy inches to be the circumference at twenty feet, and the length of the tree to be forty feet, neglecting the remaining top; then will its solid content be eighty-five cubic feet, and the value of the tree

PLANTATION.

tree at nine-pence a foot, above three guineas. But as the trees are supposed to be planted in an high, bleak, barren situation, their annual increase may not be so great as is here supposed; instead of being worth, at sixty years after planting, three guineas a-piece, admit that they are worth only ten shillings each, then would the whole plantation be worth 125,000*l.*, and deducting the whole expence, 10,600*l.* as before estimated, there would remain a profit of 114,400*l.* The present value of 114,400*l.*, to be received sixty years hence, is above 10,000*l.* (interest of money at 4*l.* per cent.) Ten thousand pounds at 4*l.* per cent. purchases an income of 400*l.* a-year: by planting then, a barren estate of a thousand acres, is improved from 4*l.* 3*s.* 4*d.* to 400*l.* a-year, reckoning the value of a reversion as a present certainty. Sixty years is a great part of the life of a man: but it ought to be considered as nothing in the existence of a nation, or even of a family, which is a little nation. The waste lands in this and other countries are a public treasure in the hands of private persons; all of them ought to be converted into arable, meadow, or pasture land, which are capable of admitting, with profit, that kind of improvement; and such of them as will not pay for that mode of improvement, ought to be covered with wood; the high parts, and especially the sheltered dells in the high parts, with larch, and the lower with oak, ash, &c.

And in making plantations of this sort, it has been advised by E. Harries, esq. of Hanwood, to attend to two circumstances, namely, situation and distance. The strong westerly winds are very apt to bend the upper part of the trees, especially if they stand single, or upon sloping grounds. To guard against this, a shelter of Scotch pines should be planted to the westward, some years before the larch. In respect to giving the plants sufficient room: in eight years they may be twenty feet high, and their lateral shoots extend two yards every way from the trunk; and they should not then be suffered to continue nearer than five or six yards; and what are left may continue to be useful building timber. At first planting, a distance of about seven feet should be allowed; they will then be furnished with sufficient lower branches, which give the tree a steady and tapering trunk. The knife should never be applied to them. There is no tree of quicker growth. He has larches that are twenty feet high in seven years growth, and sixteen or eighteen inches round. At thirty years growth, they measure from four to five feet round, at five feet from the earth.

As the larch and fir are so much in use in forming plantations, it may be proper to take some further notice of their properties. In speaking of the larch, the wood, Dr. Anderson observes, is possessed of so many valuable qualities, that to enumerate the whole would appear extravagant hyperbole. It is known to resist water, without rotting, almost for ever. The piles of this timber, on which the houses of Venice were built many hundred years ago, are still found as fresh as when first put in. Stakes of it have been tried in the decoys of Lincolnshire, which, between wind and water, have already worn out two or three sets of oak stakes, and do not yet discover any symptoms of decay. It is also known to possess the valuable quality of neither shrinking nor warping when put into work, nor is it liable to be pierced by worms in our climate. Besides, it is known to be one of the quickest growing trees, remarkably hardy, and extremely beautiful. It is much more easily reared than the oak, and could be spread over a great extent of mountains, if sufficiently bare of herbage, at little or no expence, by the natural shedding of its seeds. It would be valuable not only for ship-plank; but even crooked timbers might be obtained by using a little art to bend it when young. For

flood-gates in navigable canals and wet docks, it would exceed every thing that can be obtained in this climate; for barrel-staves it would be inimitable; and in building it would answer all the purposes to which fir is now applied, being much stronger and more durable than that wood. When it is also adverted to, that it is next to incombustible, it deserves to be strongly recommended to planters in this country, particularly in the most rugged and barren districts; where, at a very trifling charge, estates might be brought to a hundred times their present value. And that it is so much more valuable than the Scotch fir that is now universally preferred to it, for plantations of large extent, in almost every situation. That as it has only been of late introduced into Britain, the qualities of the wood are not sufficiently understood; for before the last thirty years it was cultivated rather as an ornamental tree than with a view to profit. But wherever it has been introduced, it grows so freely; is so beautiful when in leaf; so highly ornamental when covered with its abundant pink blossoms in the spring; and it is so elegant in its form, that it is sure to become a favourite with the planter. However, in the opinion of Mr. Harte, it grows slowly the first four years; but in twenty years will exceed a fir tree, both in height and circumference, that is double its age.

In making a plantation of larch, the thinnings may be applied to a variety of useful purposes, whilst they are yet of a small size. In six, eight, or ten years, according to soil and circumstances, the trees will have attained a size sufficient to be made into hay-rakes. They grow so straight, and the wood is so light, strong, and durable, as to be peculiarly calculated for this purpose; and from its shrinking less than any other wood, these rakes will remain longer firm than those made from any other. About two feet cut off from the root end will form the rake head; and five feet above that, with a very little taken off from the thickness of the under part, will form the handle. No wood is more proper for the teeth of the rake, than some of the red wood of an alder tree, because it is not only tough, but little liable either to split or shrink. The bow may be made of ash, or of the laurel-leaved sweet-scented willow (*Salix pentandra*), which is still better. Nothing is so fit for shafts to hoes; for it is nearly as strong, and much more durable than ash. Handles for brushes, brooms, scythes, &c. would occasion a vast consumption of these small spars. And light, neat, and strong chairs, for ruff bottoms, might be made of larch wood at this age. It is likewise supposed, that nothing will answer better for hop-poles; for one set of these would outlast two or three sets of ash. Hurdles, spars, and gates, may be made of it both lighter and more durable than of any other wood; and when the trees are of a sufficient size, they may be split down for cart-shafts; and in mining countries they might be employed as posts for supporting the roofs of the mines. And the small tops cut off in making these various works, would furnish a neat, elegant, cheap, and durable kind of railing, to be put upon the top of low walls, especially for preventing light sheep from overleaping them. One end might be let into the coping, whether of sod, clay, or lime; and the other end received into a slip of sawn larch wood, with holes bored through it to receive their points. From the straightness of the wood, this kind of rail would be very neat without much expence. In the same manner hen-coops, crates for packing glasses, &c. might be made of those materials. But one of the most extensive and beneficial uses of this kind of small wood, is for the purpose of inclosing. These spars, when the root is thick enough, may be slit up the middle by a saw, and cut into lengths of five or six feet; or if smaller, they may be employed whole. As they

PLANTATION.

they are always straight, and nearly of an uniform thicknes, if driven into the ground for a few inches in a row, at the distance of a few inches from each other, with the split sides all one way, they would make one of the neatest and most complete fences that can be seen. The tops of these uprights may be received into a piece of sawed plank, with holes bored in it for that purpose; and supported at due distances by sloping pieces reaching from the ground to the top.

It may, however, be noticed, that it must stand to be of a sufficient age before the timber acquires its best qualities of strength and durability. The largest of the larch trees on the duke of Athol's lawn at Dunkeld, was measured in the month of March, 1796, and the following are the dimensions of it.

At the height of	Ft. In.	from the ground, the circumference is	Ft. In.

The whole height was eighty-five feet. There are several larches upwards of one hundred feet in height, which are five or six years younger, but none of so great a girth. The largest of Mr. Drummond's was ninety-seven feet high, but less in circumference.

For a trial, the duke of Athol has applied larch to a variety of purposes, such as mill-axes, flooring in houses, window frames and doors, poits and rails, and boat-building: for all of which it appeared to answer so well, that it is the greatest acquisition of wood ever introduced into Great Britain, especially as it attains a considerable size on high grounds and bleak exposures, where even Scotch firs either die or become stunted. Fishing boats, made of larch under forty years growth, last nearly three times as long as those built of Norway fir. The late violent winds blew down a larch in the duke's lawn of fifty years of age, eighty-six feet six inches in height, containing eighty-two feet of solid wood; for which four pounds sterling was offered as it lay on the ground. And as it is not ascertained whether larch wood is capable of resisting the sea-worm; Dr. Anderson has proposed to prove it by sinking a piece of the sound, well ripened wood, with another piece of found oak wood in the river Medway at Rochester bridge, where it is well known that every other kind of wood is very soon perforated by the sea-worm.

It is therefore concluded, that on account of the valuable qualities of the wood the larch deserves to be cultivated in this country. And another recommendation of it is, its quickness of growth. Eight trees being measured in the spring and autumn of the year 1794, the average of their increase in height was nearly three feet nine inches and a quarter; and one of them increased three inches in circumference at two feet above the ground. In another plantation, the trees at eight years growth measured above twenty feet in height on an average; the trees were from six to nine inches high when planted. At twelve years old they measured, on an average, from thirty-four to thirty-six feet in height. This plantation was on a good soil and in a favourable situation. Nor is it only while the tree is young that it makes these vigorous shoots; for it appears by the measurement of the trees in Dunkeld, that this in a great measure continues even till a period of age, beyond that which they have as yet attained; for one hundred and twenty

feet in fifty years, gives an average of nearly two feet and a half in height for each year of their growth.

Very great improvements have been made in the northern parts of Scotland, by means of plantations of Scotch pine, upon the barest moors, and in the bleakest and most inhospitable situations; the returns of such plantations having been such as fully to satisfy the owners. And when the collateral advantages are adverted to, the improvements, Dr. Anderson thinks, are very great indeed; for in the neighbourhood of such plantations, houses can be reared at so little expence, and the roofs are so much better than ordinary, as to induce settlers to make their dwellings much neater and more commodious than in other places; rails and other dead fences can be so easily obtained, that poor people are first enabled to have good well fenced gardens, and then commodious inclosures of larger extent; the branches afford fuel to the settlers; cutting and manufacturing the wood furnishes employment to many; population is thereby augmented; hence a desire for land to produce the necessaries of life, and a consequent increase of rent to the proprietor. In this way Mr. George Dempster sees fields rapidly converting into cultivated grounds on his estate, and yielding to him ten or twelve shillings an acre rent, not only without any expence to him, but after having derived a considerable profit from the sale of woods of his own planting, which grew upon land that five and twenty years before was not worth, to him, above two-pence an acre, and which might have remained in that state for ages to come had it not been planted. A plantation of Scotch pine can be made at much less expence than any other tree in the northern parts of Scotland, because the young plants can be afforded at a smaller price. In Aberdeenshire, plants of two years old (and above that age no experienced planter will ever buy them) sometimes sell at four-pence a thousand, consisting of 1200; and they seldom exceed eight-pence; and there are men that will undertake to complete the whole inclosing, and planting at the distance of a yard from each other, and supply the deficiencies for five years, at the rate of from ten to thirty shillings the Scotch acre, according to the size of the inclosure, and the nature of the fence.

It is found by experience, that there is scarcely a soil so bad or any exposures so bleak, where this tree will not live, if the plantation be of sufficient extent, and not upon the very summit of high peaked hills. They do not indeed bear the sea air very well; nor is the wood ever of a good quality, or the tree long lived, upon clayey soils. Several persons in the south of England have found, that the pinaster bears the sea blast much better than any other pines. The spruce fir will bear a still more exposed situation than the Scotch pine, and after a few years it shoots up with still greater luxuriance. But the cones not being to be had in an equal abundance, and the plants being more difficult to rear, they are sold at a much higher price. Silver fir in a good soil prospers well, and is a beautiful tree, but the price of the plants is too great to admit of large plantations of them being made.

Where the situation is bleak and much exposed to strong blasts of wind, the plantation must not only be of considerable extent, but the trees be planted very close, so as to be not more than from two to three feet asunder; the more exposed the situation the closer they must be; for it is observed, that until the branches intermingle, and thus serve to give a mutual support to each other, the trees never begin to advance with vigour. Where the plantations are thus thick, there is a necessity for beginning to thin them out from the tenth to the fifteenth year after planting. Where the plantations are extensive, these thinnings sell at a small

a small price, but there are few situations in which they will not do more than pay for the expence of cutting them out. Pruning is likewise occasionally necessary in many sorts of plantations. See PRUNING, THINNING, and SHELTERING Woods and Plantations.

The leaves and branches of the Scotch pine afford a very wholesome nourishment to cattle and sheep. In mountainous countries, where snow sometimes lies upon the ground for many weeks together, the benefit that may occasionally be derived from such plantations will be very great; and the larger branches that are left make excellent fire wood in such cases.

In some districts where the soil is of the loamy and better kinds, there are often large plantations of the fruit-tree, as the apple, pear, and other sorts, in the fields, hedge-rows, &c. See ORCHARD.

PLANTATION *Screenes*, are such tracts or plats of planting as are made round plantations or other woods, for the purposes of screening, protecting, and promoting the growth of their timber trees or underwood.

They are particularly beneficial in these ways, in many exposed situations, as well as for defending the animals from the cold and cutting blasts which sweep over them, as they render the climates of such regions more mild and warm, giving a softness to the air in such exposures.

PLANTE-VER, in *Natural History*, the name of a herb sent over from China, where it is called *hiatsaotonetchom*; that is to say, a plant which at a certain time of the year changes into a worm. The Chinese say, that this is a plant during the summer season; but that in winter its stalk dies, and the root becomes a worm. M. Reaumur has well observed, that in the present improved state of natural knowledge, we can give no credit to such marvellous accounts; and of the roots sent over to the Academy at Paris, it appeared, that only a certain part of each was to undergo this change: this, however, if true, was no less a marvel than that the whole should.

Father Parenin, who sent it to France, observes, in his account of it; that it was a very scarce plant even in China; being found only at the palace of Pekin there, where also it was not native, but brought from the mountains of Tibet, and some other places on the confines of the Chinese dominions. This father had never seen the leaves or flowers of the plant, but only its roots, which were in high esteem there, not only because of their miraculous changes, but from their possessing the virtues of the famous ginseng; but with this advantage, that the use of them was not subject to be attended with those hæmorrhages which frequently affected the persons who take large quantities of that famous root. The roots of this plante-ver are usually about a quarter of an inch thick, and from an inch to three inches in length; but there are much larger in the places where they grow.

These roots had nothing particular in their figure or appearance; but with these the father sent some of those which were supposed to be changed into worms, concerning which he observed, that nothing could more exactly express a worm or caterpillar; the head, the eyes, the feet, and the mouth, being all plainly distinguishable, as well as the several folds and cuttings-in of the body. This account was found to be perfectly true; but the mistake was the want of proper accuracy in the observation; for this body, which was supposed to be the root transformed, had in reality never been any part of the plant, but was found to be really and truly a caterpillar.

This was one of the underground kind, or at least of those which go into the ground to pass their transformation: of these we have a great many different species in all parts

of Europe, and some of them, when they are entering into their nymph state, have a custom of fastening themselves to the roots of plants. Of this kind was the Chinese insect, which, when the time of its change approached, always selected the roots of this plant as of a proper size and dimension for its purpose; and, gnawing off the end, hollowed away the stump, so as to introduce its tail into the cavity; where it remains covered with the bark of the root, which so nicely joins to it, that people who observe it in a slight way cannot but mistake it to be a part of the root, or the remainder of the root a continuation of its body. The more accurate naturalists will, however, easily distinguish the vegetable fibres, which make up the root from the animal ones of the caterpillar; and to an eye accustomed to such researches, the nice joining of the tail to the remainder of the root will easily discover itself. Mem. Acad. Par. 1720.

PLANTED COAT, in the *Manege*. See HAIR.

PLANTIN, CHRISTOPHER, in *Biography*, an eminent printer, born at Mont-Louis, near Tours, in 1514, learned his art under Robert Mace, printer at Caen in Normandy. He settled at Antwerp, where he formed a considerable establishment; and at length he became one of the most eminent printers of the age. He published a number of important works, to the prefaces of which he has subscribed his name, yet it is asserted, that he had no pretensions to learning, and could not even read Latin. If, however, he was defective himself, he employed able and accurate correctors of the press, who brought his editions of literary works to great repute. The most celebrated performance that came from his press was a Polyglott bible, printed after that of Alcalá. In the course of his trade he acquired large property, which he freely employed for the service of learning and its votaries. He died at Antwerp in 1589, with the title of arch printer to the king of Spain. He possessed a fine library, which he bequeathed to his grandson Balthazar Moret. It was the custom of this period for every printer of reputation to adopt a motto, which he inserted in the title-pages of his works. The device of Plantin was a pair of compasses, with the motto "Labore et Constantia." Moreri.

PLANTING, in *Gardening*, the operation of inserting plants of the fruit-tree and other kinds, seeds, and roots, into the earth, for the purpose of vegetation and future growth.

There are various methods of performing this business in practice for different sorts of plants, seeds, and roots; as hole planting, trench planting, trenching-in planting, slit or crevice planting, holing-in planting, drill planting, bedding-in planting, furrow planting, dibble planting, trowel planting, planting with balls of earth about the roots, planting in pots, &c., all of which are occasionally used by different practitioners in the several branches of gardening, according as the methods are most proper for different particular sorts of plants.

In the *first*, or *Hole Planting*, which is the principal method practised with most sorts of trees and shrubs in the full ground, and which is performed by opening with a spade round holes in the earth, at proper distances, for the reception of the plants, each hole should be dug large enough to admit all the roots of the tree or shrub freely every way to their full spread, without touching the sides of the hole, and about one spade deep, or a little more or less, according to the size of the roots and nature of the soil, so as, when planted, the uppermost ones may be only about three or four inches below the common surface, or as low as they were before in the ground; though in very humid soils, where the water is apt to stand, the holes should be shallower, so as the uppermost roots may stand

PLANTING.

full as high as the general level, or higher if necessary, raising the ground about them, especially when performed in winter. When the soil has been thus dug out, the bottoms should be well loosened; the mould in digging out being laid in a heap close to the edge, in order to be ready to fill in again. The holes being thus prepared, and having slightly trimmed the roots, &c. of the trees, one tree or plant must be placed in the middle of the hole, making all its roots spread equally around; a person holding the plant erect by the stem, while another with the spade casts in the earth about the roots, taking particular care to break all large clods, and trim in some of the finest mould first all round the roots in general, shaking the tree occasionally, to cause the fine soil to fall in close among all the small root fibres; and where the tree stands too deep, shake it up gently to the proper height, and having filled in the earth to the top of the hole, it should be trodden gently all round, first round the outside to settle the earth close to the extreme roots, continuing the treading gradually towards the stem, to which the mould should be pressed moderately firm, but no where too hard, only just to settle the earth, and steady the plant in an upright position: then all the remaining earth should be pared in evenly round the tree, to the width of the hole, raising it somewhat above the general level of the ground, to allow for settling, giving it also a gentle treading; and finishing it off a little hollow at top, the better to receive and retain the moisture from rains, and giving occasional waterings in spring and summer, especially for the choicer kinds of trees and shrubs.

After this, in winter, or early in spring, it may be of advantage to the choicer kinds of trees and shrubs, to lay some long mulch at top of all the earth, both to keep out the winter's frost, and prevent the drying winds and drought of spring and summer from penetrating to the roots before the trees are well rooted in their new situations. But some, instead of mulch, use grafs turfs turned upside down, especially when planting upon grafs ground, or any out-plantations, where turfs of grafs can be obtained; or in orchards, where the ground is in grafs; in which case it may be proper to bank some turfs round the sides and top of each hole, particularly for large trees; which will steady them more effectually, as well as preserve the moisture, if much dry weather should happen the succeeding summer.

In the second, or Trench Planting, which is a method sometimes practised in the nursery, in putting out seedlings and other small trees and shrubs in rows; and also used for box edgings, as well as sometimes for small hedge-fets, &c. and always in setting out asparagus; it is performed by opening a long narrow trench with a spade, making one side upright, then placing the plants against the upright side, and turning the earth in upon their roots. When used for young seedlings, or other small trees, shrubs, &c. the ground is previously trenched or dug over: a line is then set, and with a spade held with its back towards the line, a narrow trench six or eight inches deep is cut out, turning the earth from the line, making the line side nearly perpendicular: the plants are then inserted in the trench at small distances, close to the upright side, covering in the earth about the roots in planting them; and having planted one row, the earth should be evenly trodden in all the way along, to settle it close, and fix the plants steady, proceeding from row to row in the same manner.

But in planting larger trees, in the nursery way, by this method, a larger trench will be requisite; sometimes a trench one or two spades wide, with proportionable depth, according as the roots of the trees require, is made; and having opened it all the way along the intended row, the trees are placed along the middle of the trench, filling in

some earth to each tree, as placed, one person holding it erect, whilst another throws in the earth; and having placed one row, trim in all the remaining earth evenly; then treading it closely all the way to fix the plants steady, and in a perfectly upright manner.

In the third, or Trenching-in Planting, which is also sometimes practised in light pliable working ground, for young trees in the nursery way, and sometimes with edge-fets, &c., being performed by digging along by a line, about one spade in width, and planting at the same time; a line is set; and then having the plants ready, with a spade begin at one end, and standing sideways to the line, throw out a spit or two of earth; which forming a small aperture, another person being ready with the plants, he directly deposits one in the opening, while the digger proceeds with the digging one spade wide, covering the roots of the plants with the earth of the next spit; and another aperture being thus formed, another plant is placed in: the digger, still proceeding, covers its roots, as before, with the next spit of earth; and so on to the end of the row, placing them at about a foot, or fifteen or eighteen inches asunder, according to the size of the plants. When larger trees with more spreading roots are used, instead of digging the trench only one spade wide, two may probably be requisite for the proper reception of the roots; likewise, in forming the openings for the plants, they should be made large enough to receive the roots freely, digging the earth over them as above. After having planted one row of plants, the earth should be trodden evenly along to settle it to the roots, and steady the plants in an upright position. There is another method of this sort of planting, sometimes used for some sorts of roots, such as horse radish fets, potatoes, &c., which is performed by common trenching, placing a row of fets in each trench. The horse radish should be planted in the bottom of the open trench, twelve inches in depth, turning the earth of the next over them; and the potatoe fets be placed about from four to five or six inches deep, covering them also with the earth of the next trench.

In the fourth mode, or that of Slit Planting, which is performed by making slits or crevices with a spade in the ground, at particular distances, for the reception of small trees and shrub plants, a slit is made for each plant, which is inserted as the work proceeds; and is practised sometimes in the nursery way, &c., in putting out rows of small plants, suckers, &c., at from about a foot to eighteen inches or two feet high, and which have but small roots: it is also sometimes practised in out grounds, where large tracts of forest trees are planted, and which are planted out at the above sizes, and in the most expeditious and cheapest method.

It is performed in this manner: a line is set, or a mark made; and then having a quantity of plants ready, they are planted, as the work proceeds in making the slits. A man, having a good clean spade, strikes it into the ground with its back close to the line or mark, forming a crevice, taking it out again directly, so as to leave the slit open, giving another stroke at right angles with the first; then the person with the plants inserts one immediately into the second-made crevice, bringing it up close to the first; and directly presses the earth close to the plant with the foot; proceeding in the same manner to insert another plant; and so on till all is finished; which is a very expeditious way of putting out small plants, for large plantations, but should never be employed, where other better methods can be used.

A man and a boy in this method will plant out ten or fifteen hundred plants, or more, in a day.

PLANTING.

In the fifth, or Holing-in Planting, which is sometimes used in the nursery, in light loose ground: also, sometimes with potatoes, &c., in pliable soils; the ground being previously dug or trenched, and a line placed: it is thus performed; a person with a spade takes out a small spit of earth, to form a little aperture, in which another person directly deposits a plant, &c., the digger at the same time taking another spit at a little distance, turns the earth thereof into the first hole over the roots: placing directly another plant in the second opening, the digger covers it with the earth of a third spit, and so on to the end of the row.

In the sixth, or Drill Planting, which is by drawing drills with a hoe from two to four or five inches deep, for the reception of seeds and roots, and is a convenient method for many sorts of large seeds, such as walnuts, chestnuts, and the like; sometimes also for broad beans, and always for kidney beans, and peas; likewise for many sorts of bulbous roots, when deposited in beds by themselves; the drills for these should be drawn with a common hoe, two or three inches deep; and for large kinds of bulbous roots, four or five inches in depth, covering in the seeds and roots with the earth, always to the depth of the drills.

In the seventh, or Bedding-in Planting, which is frequently practised for the choicer kinds of flowering bulbs, such as hyacinths, &c., also for the larger seeds of trees, as acorns, large nuts, and other large kinds of seeds, stones, and kernels: it is performed by drawing the earth from off the tops of the beds some inches in depth, then planting the seeds or roots, and covering them over with the earth, drawn off for that purpose; for which the ground should be previously dug or trenched over, raked, and formed into beds three or four feet wide, with alleys between; then with a rake or spade trimming the earth evenly from off the top of the bed into the alleys, from two or three to four inches deep for bulbous roots, and for seeds, one or two, according to what they are, and their size; afterwards, for bulbous roots, drawing lines along the surface of the bed, nine inches distance, placing the roots bottom downward, along the lines, six or eight inches apart, thrusting the bottom into the earth: but when for seeds, they may be scattered promiscuously; and having thus planted one bed, then with the spade let the earth, that was drawn off into the alley, be spread evenly upon the bed again over the roots or seed, &c., being careful that they are covered all equally the above depth, raking the surface smooth and fine.

This method is in occasional practice, in planting several kinds of the larger prime sorts of bulbous-rooted flowers in beds; and nurserymen also practise it in planting many of their larger seeds, nuts, &c.

And another method of this kind is occasionally practised in some parts, particularly for planting potatoes in low wet grounds, which is by dividing the ground into beds, four feet wide, with alleys two or three feet in width; then digging the beds, and placing the potatoe-sets in three rows along each bed, a foot asunder in the rows: this done, the alleys are dug one spade depth, casting the soil upon the beds over the sets, so as to cover them four or five inches deep; in this way, where the ground is very wet, the alleys drain the moisture from the beds, so as sometimes to afford great crops. Sometimes, in low moist grounds, that are in grass or sward, the beds are marked out as above, and without digging the ground; placing the potatoe sets immediately upon the sward, then digging the alleys, first turning up the sward, and placing it topsy-turvy upon the bed, so as to be sward to sward over the sets; then finishing by applying more earth from the alleys, to cover

in the sets, the proper depth of four or five inches. This, in some counties, is called the lazy-bed method, because the ground is not dug over.

In the eighth, or Furrow Planting, which is by drawing furrows with a plough, and depositing sets or plants in them, covering in also with the plough: it is sometimes practised for planting potatoe-sets in fields, and has been adopted in planting young trees for large tracts of forest-tree plantations, where the cheapest and most expeditious method is required; but this method can be practised only in a light pliable ground, and is performed thus: a furrow being drawn, one or two persons are employed in placing the sets or plants in the furrow, whilst the plough following immediately with another furrow, turns the earth upon the roots of the plants. This is not a mode to be much advised.

In the ninth, or Dibble Planting, which is the most commodious method for most sorts of fibrous-rooted seedling plants, particularly all the herbaceous tribe; also for slips, offsets, and cuttings both of the herbaceous and shrubby kinds; likewise for some kinds of seeds and roots, such as broad beans, potatoe sets, Jerusalem artichokes, and horse-radish sets, with numerous sorts of bulbous roots, &c.; it is expeditiously performed with a dibble or setting-stick, by making a narrow hole in the earth for each plant, inserting one in each hole always as the work proceeds.

Having a dibble or setting-stick, it is used by thrusting it into the earth in a perpendicular descent, in depth as the particular plants, &c. may require; directly inserting the plant, seed, or set, as each hole is made, closing it immediately by a stroke of the dibble. In setting any kind of plants, slips, cuttings, &c., having long shanks or stems, it is proper to make holes a proportionable depth, to admit them a considerable way in the ground: for example, cabbage-plants, favoys, &c. should be planted down to their leaves; slips and cuttings should be inserted two parts of three, at least, in the ground; being particularly careful in dibbling-in all sorts of plants, to close the holes well in every part about the roots; by striking the dibble slantways into the ground, so as to strike the mould first firmly up to the root and fibres, at the same time bringing it close to the stem. See **DIBBLE**.

In the tenth mode, or Trowel Planting, it is performed with a garden trowel, made hollow like a scoop, and is useful in transplanting many sorts of young fibrous-rooted plants with balls of earth about their roots, so as not to feel their removal.

The trowel is employed both in taking up the plants and planting them.

In the eleventh, or Planting with Balls of Earth about the Roots, which is the removing of the plant with a large ball of earth about its roots, so as by having its roots firmly attached to the surrounding earth, it still, during the operation, continues its growing state, without receiving any, or but very little check from its removal: this is often practised more particularly for the more delicate and choicer kinds of exotics, trees, shrubs, and herbaceous plants; and occasionally for many of the fibrous-rooted, flowery plants, annuals, perennials, and biennials, even in their advanced growth and flowering state, when particularly wanted to supply any deficient compartments; though it is not so eligible for bulbous-rooted kinds: likewise, when intended to remove any sort of tree or plant out of the proper planting season, as very late in spring, or in summer, it is proper to transplant it with a good ball of earth, to preserve it more certainly in a state of growth. Some trees and shrubs are more difficult to remove with a ball than most kinds of the herbaceous fibrous-rooted plants,

PLANTING.

though many of the tree and shrub kinds having very fibry roots, also readily rise with good balls.

In transplanting any of the tree and shrub kinds by this method, if they grow in the full ground, the operator must be careful to begin to open a trench with a spade at some distance from and round the stem, perhaps a foot, or two or three, according to the size of the tree and expansion of the roots, digging a sort of trench all round, a spade or two wide, or more if large trees, and in depth below all the roots; all the time having great care not to disturb the ball or mass of earth between the stem and trench, but preserve it as entire as possible. When the whole has been detached, the plant should be removed into the situation for which it is intended, with the whole of its ball about its roots.

When trees or shrubs, with balls to their roots, are intended to be sent to considerable distances, they should be placed singly in osier baskets, in order to preserve the ball, having a basket for each tree; the baskets to be of an upright make, in width and depth in proportion to the ball, with two handles at top, especially if large, and generally worked rather open at the sides, as sometimes the basket and all is placed in the ground, when the plant cannot be readily removed without danger of breaking the ball of earth about it.

In respect to the method of planting in pots in general, having the pots and mould ready for the reception of the plants, previous to planting them place some pieces of tile, pot-sherds, or oyster-shell, &c. over each hole at the bottom of the pots, to prevent the holes being clogged and stopped with the earth, and the earth from being washed out with occasional waterings; also to prevent the roots of the plants getting out: then having secured the holes, put some earth in the bottom of each pot, from two or three to five or six inches or more in depth, according to the size of the pot, and that of the roots of the plant; then insert the plant in the middle of the pot upon the earth, in an upright position, making its roots, if without a ball of earth, spread equally every way; directly adding a quantity of fine mould about all the roots and fibres, shaking the pot to cause the earth to settle close thereto: at the same time, if the root stand too low, shake it gently up; and, having filled the pot with earth, press it gently all round with the hand, to settle it moderately firm in every part, and to steady the upright posture of the plant, raising the earth however within about half an inch, or less, of the top of the pot, as it will settle lower; for some void space at top is necessary to receive waterings occasionally: as soon as the plant is thus potted, give it directly a moderate watering to settle the earth more effectually close about all the roots, and promote their rooting more expeditiously in the new earth; repeating the waterings both before and after they have taken root, as occasion may require.

In transplanting plants in pots from one pot to another, they may in general be shifted with the whole ball of earth contained in the pot about their roots entire, so as to preserve the plant all along in its growing state, as scarcely to shrink or retard its growth by the operation; for plants growing singly in pots, and of some standing, whose roots and fibres have established themselves firmly in the earth, will readily remove out of the pots with the entire ball in one compact lump, surrounding all the roots and fibres, retaining their growing state by still drawing nourishment from the surrounding ball of earth.

The removing of plants from one pot to another with balls, is in some cases to be avoided; as where a plant appears diseased or in a bad state of growth, as it is most probable the fault is in the root of the earth; therefore, it is

eligible to shake the whole entirely out of the earth, in order to examine its roots; and trim off all decayed and other bad parts; then, having a fresh pot, and some entire new compost, replant the tree, &c. therein.

In potting plants from the full ground, or beds of earth, &c., if they have been previously pricked out at certain distances, and have stood long enough to fix their roots firmly, many sorts may be potted with balls, particularly most of the herbaceous, fibrous-rooted kinds, and many of the shrubby tribe, by taking them up carefully with the garden trowel, or with a spade, as may be convenient, according to the size of the plants; and, if necessary, pare the balls round to fit the pot.

Seedling plants, or those raised from seed beds, by their growing to close together, rarely admit of potting with balls to their roots; so that when it is intended to pot such, they must be drawn out of the earth with the root as entire as possible, and be potted separately in small pots, shifting them occasionally into larger.

Sometimes in pot-planting, to save room, and for other purposes, several small plants are planted in each pot, especially when designed as nursery-pots, to receive either small seedlings, offsets, slips, cuttings, &c., just to strike them, and forward them a little at first, either in hot-beds, or for removing them to different situations, such as occasional shade, shelter, &c., and in which some sorts of small slips and cuttings are sometimes planted many together, in one or more wide pots, especially where large supplies of some particular sorts are required, such as myrtle cuttings and pipings of pinks, &c., sometimes to the amount of a hundred or two of these small sets in one capacious pot or wide store pan. The small seedlings, slips, cuttings, offsets, &c., when they are a little forwarded, or properly rooted, and shoot a little at top, should be all potted off, in proper time, each in a separate pot, especially if plants of any duration; giving them small pots at first, and as they increase in size shifting them into larger ones.

When any large growing plants, such as orange and lemon trees, or any other kinds, are become too large for pots, they should be shifted into tubs: these tubs should be made of full-inch thick staves, and adapted to the size of the respective plants; each tub to be well hooped with iron, and furnished with two hooked or bow iron handles at top, by which to move them, either by hand, or, when very large tubs, to receive poles between two men for moving the plants where wanted; having holes at the bottom of the tubs to discharge the superfluous moisture; placing some stones, &c. to prevent the holes being clogged with the earth; the method of planting and transplanting being the same as in pot planting.

The twelfth Method, or Planting in Pots, is practised to all tender exotics, in order for moving them to shelter occasionally, such as all kinds of green-house and hot-house plants; and likewise for many sorts of hardy flowering plants, for the convenience of moving them occasionally to adorn particular compartments; and for the convenience of moving some curious sorts when in flower to occasional shelter from the sun's rays and excessive rains, in order to preserve their beauty and prolong the time of their bloom; such as the fine auriculas, carnations, &c.

In planting in this way, it is highly requisite carefully to adapt the sizes to the size and nature of the different plants intended to be potted: if small plants, begin first with small pots, one plant only to each pot, especially if to remain; but according as the different plants advance in growth shift them into pots one or two sizes larger, which may be requisite to many sorts once a year, to others once in two or three years, according to circumstances.

PLANTING.

Garden pots for this use are of several regular sizes, from two to sixty in a cast, distinguished at the pot-houses accordingly; as twos, sixes, twelves, sixteens, twenty-fours, thirty-twos, forty-eights, sixties, or sixty-fours, &c., each pot having one or more apertures at bottom to discharge the superfluous moisture. They are sold by the potters at so much *per cast*; large and small, all of a price; those of only two in a cast the same as those of sixty; and from two shillings to half a crown or three shillings *per cast* is the general price. See *POT, Garden*.

Sometimes, instead of baskets, small young trees and other plants with balls, intended to be sent to any distance, are put separately in pots, and when they are to be placed in the full ground, each should be turned out of the pot with the ball entire.

Trees and other plants that have generally grown in pots, where they have been of some standing, have the whole earth by means of the numerous fibres formed into one compact lump, so that it will readily come out entire and firm; or to such as do not so easily quit the pot, a long blade of a knife, or some other thin instrument, may be thrust down between the outside of the ball and pot all round, and it will then readily come out, either in drawing by the stem of the plant, or by striking the edge of the pot with something; or, if small plants, you may turn the pot mouth downward, and strike the edge gently against any firm substance. In replanting those potted plants, if the sides of the ball of earth are much matted with the fibres of the root, it is proper to pare off the grossest part, together with a little of the old earth, especially if to be planted in pots again; then put it in a pot a size larger than before, filling up all round with fresh mould, finishing with a moderate watering.

With respect to the proper state and preparation of trees for planting, it may be observed that young trees, both of the fruit and forest kinds, are the most suitable, and succeed best, as from three or four to six or eight feet in height, and from three or four to five or six years old. See **FOREST, DWARF, and STANDARD TREES.**

In forest-trees, the straightest, most vigorous, and thriving plants of the respective kinds should always be chosen.

In preparing for planting, in taking up the trees out of the nursery, the greatest care is necessary in raising them with as great a spread of root as possible, which is often ill attended to, especially when large orders of plants are to be drawn in a hurry. The ground about the trees should always be opened with the spade widely round the roots, and deep enough to get to their bottoms without hacking and cutting them with the spade, but so as to raise each plant with all its roots as entire as possible. After having taken up the trees out of the nursery, &c., it is also of great moment to have them replanted as soon as possible in the places allotted for them; for although by properly covering the roots with litter, or, if sent to any considerable distance, by tying them in bundles, and packing them up with plenty of straw about the roots, and afterwards closely matted round, they may be preserved in tolerable good condition a fortnight or longer, yet, where it is possible to plant them the same day, or in a day or two after, before the small fibres are shrunk or dried, it will be of much advantage in the first growth of the trees; but when this cannot be done, they should be immediately laid in the ground in a trench.

In preparing for planting, the roots must have occasional trimming, not however to retrench or reduce any but the maimed and decayed parts; therefore previous to planting examine the root, and cut out all such parts as have been broken or damaged in taking up, and any casual decayed parts or other blemishes, being careful to leave all the found

roots every where entire; leaving also all the small fibres that are fresh and vigorous, only trimming off such as are become dry and mouldy; suffering all the main roots to remain, mostly at full length, except just to tip off their ends a little on the under side, sloping outward; and reduce any very long stragglers, and shorten long perpendicular tap-roots, more particularly of fruit-trees, to prevent their running down into a bad soil, and to promote their throwing out others horizontally.

With regard to the preparation of the heads of the trees, the principal care is to trim off the straggling shoots and branches from the stems, leaving the heads for the generality entire, only just retrenching very irregular branches, and shortening any very long stragglers; always suffering the main or leading top shoot to remain at length, particularly in forest-trees, and all others that are to grow to a lofty stature. Fruit-trees, however, sometimes require a more accurate regulation of the head preparatory to planting, particularly dwarfs for espaliers and walls. If the fruit-tree is taken from the nursery at one year old from the budding and grafting, and with its first shoot from budding and grafting entire, this first shoot must necessarily be shortened or headed down to force out lateral wood below, to furnish the bottom properly; but this heading down is not necessary at the time of planting, but should remain till spring, until the tree has taken fresh root and begins to shoot; for the head remaining greatly promotes the rooting; when in March or the beginning of April, head it down within half a foot, or five or six eyes of the insertion of the bud or graft, and the shoot so headed will throw out, from its remaining lower eyes, several lateral branches the ensuing summer.

If it is two, three, or more years old from the budding and grafting, and the first shoots were headed down in the nursery at the proper time, it is proper to plant it with its whole head entire, only retrenching any irregular branch, or any very luxuriant shoot; or thin out the worst of such as are evidently too close or crowded, leaving however all the regular branches at full length, except just to reduce any very long Rambler.

For new planting trees it is very improper to retrench the branches too severely, and cut all that remains short, as is very often practised, on a supposition of strengthening their roots, which however has often the contrary effect; for the branches and leaves imbibe the refreshing influence of the air, &c., which, being conveyed to the roots, proves nutritional, and contributes exceedingly towards vegetation, and consequently promotes the rooting afresh more expeditiously and effectually. Besides, by a severe retrenching, and a general shortening, of fruit-trees in particular, in most sorts the very parts where fruit would have been soon first produced are cut off, and it will probably cost the tree two or three years growth to furnish new branches equal to those cut away, as well as retard its bearing in proportion. And it often happens by such a general amputation of the branches of all new planted trees at the time of planting, that they, for want of branches to collect vegetative nourishment, either make very little progress in shooting for two or three years after, or sometimes, when they do shoot, throw out a profusion of unnecessary wood from the remaining eyes or buds.

Therefore if young fruit-trees at planting, whether dwarfs or standards, are furnished with five or six or more good regular principal branches, of one, two, or more years growth, it is improper to retrench any part of them, and disfigure the tree, particularly apples, pears, plums, and cherries, which should at all times be but sparingly shortened; and since several good branches being already obtained in the proper parts to give the head its first regular form, they in

PLANTING.

their turn readily furnish more; and if there is a vacancy in any part, it will be better to endeavour to fill it by stopping some of the young shoots produced the summer after planting, by either pinching or pruning them in May or June the same year to three or four eyes, or cutting them down to that length in the winter or spring following. Some fruit-trees, however, such as peaches, nectarines, &c., against walls, require most of their young shoots to be shortened annually.

Forest-trees, &c., in their preparation previous to planting, after being drawn out of the nursery, should only have the blemished roots trimmed, and all branches from the lower part of the stem pruned off, cutting the lower ones close, the others to two, three, or four inches, particularly the deciduous kinds, leaving the head always tolerably branchy, and mostly entire; not to trim away all the branches to one leading shoot only, as is often practised, but leave a proportionable share of the upper more erect branches, to form some tolerable head, and only just retrenching the lower stragglers, very long rambling luxurians, and very irregular growths, to preserve a little regularity; being particularly careful to leave always the top or leading shoot perfectly entire, unless it is decayed, or is very crooked, bending much downwards, &c., in which cases, if any straight shoot is conveniently situated, the crooked part may be retrenched down to the straight shoot, which leave entire to run up in height, as without a leader a tree can never aspire to any considerable stature; for the leader, by its annual erect shoot, gradually increases the length of the stem, and, as it advances, sends out a supply of laterals to furnish the head, branching and spreading.

In planting large tall trees, where it is designed to form shade, shelter, or blind as possible, very little reduction of the branches of the head should be suffered, only to reduce any very irregular growers.

In removing pretty large trees of any sort with considerable heads, especially when very spreading or crowded, it may be proper to reduce the whole regularly in some proportion to the root, that the winds may not have too much power to incommode it after planting; in which cases it may be necessary to retrench or reduce some of the most extensive lower branches, and thin out some where much crowded, reducing others down to some convenient lateral branch they may support, so as each reduced branch may, notwithstanding its reduction, terminate in a leader, having its top entire, not to exhibit naked ends of branches, standing up like stumps.

In respect to the preparation for planting of all the shrub kind, only just trim the straggling under branches and shoots from the lower part of the stem, retrenching any luxurians of the heads that seem to shoot away very irregularly and vigorously at the expence of the neighbouring branches, and reducing long ramblers, &c., just to preserve a little regularity.

All new planted tall trees should be staked as soon as planted, in order to support them steady every where till they are well rooted and have somewhat established their roots, that winds may not overset, or otherwise incommode them; particularly all trees of six, eight, or ten feet high, and upwards; one tall stout stake being placed to each tree, or more, if the trees are of large size, sharpening the lower ends, and driving them firmly into the ground near the stem; or if larger trees, place it slantways, at a little distance, so as its top reach the upper part of the stem, on the opposite side to that most exposed to the winds, in which it will have the greatest effect; but large trees with full heads, should generally have very tall strong stakes, three to each tree, placed triangular-ways, in an oblique or slant-

ing direction, afterwards binding the stems of the trees firmly to the stakes, previously wrapping some soft substance, such as hay-bands, &c., round them, at the part where it is to be fastened to the stakes, in order to save the bark from being rubbed off against the stakes by the motion of the winds, which is more particularly necessary to tall plants that are much exposed. Large trees of considerable stature, with full heads, are often supported with ropes suspended from the top of the stem three different ways, straining them tight, and the end of each rope staked securely down to the ground; so that whatsoever way the wind blows the ropes stay the tree still in its upright position.

Such new planted trees as are exposed to cattle should each be well fortified all round the stem with thorn bushes, briars, furze, &c.

The general season of planting, for all sorts of trees, is autumn and spring, as from the beginning of the decay of the leaf, in October, until December, for the former; though evergreens may be begun to be transplanted towards the middle or latter end of September, and continued till December. And for the spring planting, February and March are the principal time, but may be continued occasionally until April; and several sorts of tender young evergreens succeed best when planted the beginning of that month, or later. Much, however, in this business, must depend on the soil and state of the weather.

In preparing to plant herbaceous fibrous-rooted plants, care is to be had to remove them with good roots; young seedlings, &c., especially require particular care in drawing them with proper roots. When they are to be taken all clean up, they may be readily loosened and raised out of the earth with some instrument with all their fibres entire; but when they are only to be thinned, they do not admit of this, as it would disturb the remaining plants, so must be drawn out by hand carefully, with as much root as possible.

Many sorts of fibrous-rooted plants, however, are so hardy, and apt to grow, that if taken up almost any how, with a little root, they will strike; it is nevertheless advisable to use care in drawing all sorts for planting with tolerable roots, as they will, in proportion, make more progress in their future growth. And as to any trimming preparatory to planting, very little is wanted, only in some sorts, just shortening very long naked spindly roots, and trimming any straggling fibres; though in numbers of plants of this tribe hardly any trimming at all is required, either in root or top.

PLANTING Timber Trees, in Rural Economy, the act of making plantations with these sorts of trees, which is a practice that has lately been more attended to than formerly; probably from the advantages of it being more fully understood, and more correctly ascertained. The particular sorts of land that may be converted to this purpose with the greatest chance of profit, have been already pointed out.

In the accomplishing the business, the principal difficulty consists in properly adapting the trees to the nature of the soil, as, unless that be the case, the success is far from so great as it would otherwise be. The land should also be in a proper state of preparation for the reception and growth of the trees, and the work be executed at a proper season in a proper manner, and at suitable distances, according to the nature and quality of the soil, and that of the trees; the whole being well fenced from the attacks of cattle.

Soil.—The particular kinds of soil best adapted to the cultivation of the different sorts of timber trees, and in which some or other of them will be found to grow in the most perfect manner, are gravelly or light sandy soils, with free porous subsoils; gravelly or sandy loams on porous subsoils; loamy,

PLANTING.

loamy, sandy, or gravelly soils on retentive subsoils; gravelly, chalk or chalky loams on porous subsoils; loamy clays or clayey loams on porous subsoils; and strong clayey or loamy soils on retentive subsoils. Likewise, thin moorish heathy soils on gravelly or porous subsoils, also on clay or retentive subsoils; and besides these kinds of land, there are, as has been seen above, many other thin poor sorts of waste, in different parts of the kingdom, which are not fit for raising any other descriptions of plants, that might be converted with great advantage to this purpose, as the diminution in the quantities of timber and other wood every where now almost begins to be seriously felt.

Mr. Smith, in the "Survey of Argyleshire," states, that the grounds there which ought to be marked out for this improvement, are such as are mentioned below. The best land would no doubt bear timber best; and if arable land could be spared for the purpose, the return might be expected to be in proportion to the value of the soil. But in this county little or no arable land, meadow, or good pasture, ought to be laid under planting. It should have only those waste grounds which are capable of this improvement, and of no other. And of these we may reckon, first, those extensive dry moorlands and moor-lands, in the hollows and on the declivities of hills, especially in the inland parts of the county. These lands are generally covered with short heath, mixed with so little grass, that they are not worth 6*l.* the acre. The trunks of trees generally found in them give, however, a sufficient proof of their aptitude to grow timber, and they can never be turned to better account than by planting them; and that with the same kind of timber that is found in them. This is generally fir, and sometimes oak. Whatever it be, follow nature, and you cannot err. It may be said that some of these situations are far from water-carriage. But the whole county is so indented with seas, and so well accommodated with roads, that almost every mountain is accessible by the one or the other. Or, if any of them be not, still it may be profitable to plant it, were it only with a view of converting a great part of the wood to the purposes of extracting from it turpentine, tar, pitch, rosin, and of making pot-ashes. And another kind of ground which ought to be planted, and of which we have large tracts, is that which is covered with brush-wood, such as hazel, birch, &c. seldom allowed by the cattle to rise above two or three feet high. Here nature, which could not be mistaken in the soil, has planted wood, though it has not been allowed to grow, and has marked out the ground as fit for planting. This brush-wood will prove an excellent nurse to young plants, by giving them shelter till they raise their heads above it; after which they will destroy the brush-wood by excluding the sun and air from it, and reduce it to a manure which will help their growth. Among this brush-wood, however, there may sometimes be found some sprouts of oak and ash, which ought to be cut over a few inches above the ground; after which they will shoot up, and thrive exceedingly, from the abundance of roots which they have to nourish them. Patches of dwarfish oak, which the cattle never allow to rise one foot from the ground, are also common in many parts of the county. If these spots were brought within the enclosure of a plantation, and the bushes cut over a little above the surface of the ground, they would soon be valuable. In England, even oak plants are often cut in this manner after one or two years, when they have taken to the ground, and the second shoot is trusted to for the tree; as it is found to grow with greater luxuriance than the first, which was checked by transplanting.

Stools of natural wood, wherever they are, furnish much room for planting; and at a trifling expence, when they are

already enclosed. Every vacancy in them ought to be filled up with oak, ash, elm, and other valuable kinds of timber. The ground is suitable for planting; the natural wood will shelter it; and thus it will thrive well, and improve the copice. The properest time for improving a natural wood with planting, is immediately after it is cut, when the fences are in best repair, and when the sun and air will get at the plants which may be set among bushes of less value. These bushes should afterwards be cut down, if they are found to hinder the growth of the planting. The duke of Argyle has done much in this way, and Lord Stonefield, sir James Campbell, and several other proprietors, have thus improved their natural woods very considerably. In one year, captain Campbell, of Kintarbet, with a spirit yet uncommon amongst the most of the proprietors of this county, planted among his natural woods no less than 20,000 trees of valuable timber. At this rate, he will, in a few years, lay the foundation of a sure and large fortune.

And a fourth kind of ground, that should be devoted to planting in this situation, is, that on which a number of venerable native firs are still growing. These memorials of our former forests are not unfrequent in some of the upper parts of the county, particularly in Glenety and Glenurchay; and they deserve more attention than they have hitherto met with. From the feed which they shed in winter, and which is driven to a distance by the storm, a beautiful plantation rises up in the spring; but when the cattle are driven up to the mountains in summer, this precious crop, the hope of future forests, is for ever destroyed. This is the more to be regretted, as the quality of this fir is so excellent, as not to be surpassed by any in the world. The feed of this fir is precious, and a single cone of it, if possible, should not be lost. But then, in order to preserve its valuable quality, it should be sown where it is meant it should grow, without passing through the medium of a feed-bed or nursery. And it appears necessary, in order to preserve the quality of the timber, that we should follow nature, and sow the seed directly where we intend the tree should grow. The seed too will thrive where plants would fail.

After some hesitation about parting with any thing we call arable ground, he mentions one other kind of land, which it may sometimes be proper to devote to planting. He means some high fields, which, under the old system of cultivation, were subject to the plough, but never to much advantage. These poor gravelly fields were manured by folding cattle on them at night. But now, where this system is given up, they lie neglected, and many of them are already covered with heath. With little expence, and much advantage, they might be converted to plantations. The earthen dikes which surround them might be faced with stones, of which the dikes themselves would furnish a great proportion. The tops of the dikes might be planted with firs, if not with quicksets, for more fence and shelter. The fields should then be ploughed, and, if at all convenient, dressed with some lime or other manure, and sown with the seed of the native Scotch fir, and with acorns. By this preparation of the ground, the trees would thrive amazingly, and the wood retain its native quality. There are many thousand acres of waste land in this country as well as Scotland, that might be converted to plantations with great advantage, and which are fit for nothing else.

A tabular view, taken, with some alteration, from the Agricultural Survey of the County of Kent, shewing the nature of the soil in which different sorts of timber trees are found to succeed in the most certain and perfect manner, with the uses to which they may be applied in different cases, is given in the following table.

PLANTING.

Surface Soil.	Subsoil.	Common Growth.	Planted Growth.	Uses of.
Heavy and gravelly loams.	Heavy loam with chalk.	Birch, hornbeam, oak, ash, hazel, beech, &c.	Oak, ash, chefnut, willow, lime, walnut.	Timber, hop-poles, cord-wood, hurdles, bavins for bakers, and lime.
Sandy loams.	Heavy loams.	Birch, hornbeam, oak, ash, hazel, beech, &c.	Elm, beech, Weymouth pine, common spruce.	Timber, hop-poles, cord-wood, hurdles, bavins for bakers, and lime.
Flinty strong loam.	Heavy loam.	Ditto.	Willow and chefnut.	Timber, fencing-poles, and as above.
Gravelly and sandy loams.	Gravelly loam.	Ash, beech, oak, hazel, &c.	Chefnut, ash.	Hop-poles, fencing-poles, and all as above.
Gravelly, sandy and flinty loams.	Heavy gravelly flinty loam.	Ash, beech, hornbeam, and oak.	Ash, beech, larch, &c.	Timber, fencing, hop-poles, cord-wood, for charcoal, bavins, &c.
Flinty dry poor gravelly loams.	Chalk at two feet depth, with gravelly loam.	Beech, oak, &c.	Beech, larch, &c.	Cord-wood, bavins, and hop-poles.
Flinty and gravelly loams.	Chalk four feet, with deep gravelly loam.	Ash, oak, hazel, &c.	Ash, larch, &c.	Cord-wood, hop-poles, bavins, stakes, ethers, &c.
Ditto.	With a few flints, but nearly as above.	Oak, hazel, beech and ash.	Chefnut, ash, and willow.	Hop-poles, fencing-poles, stakes, cord-wood, &c.
Lightish black loam.	Dry sandy gravel.	Birch, elm, ash.	Ash, elm, &c.	Various uses in husbandry.
Flinty gravelly loams.	Strong loam, with flints.	Oak, ash, beech, &c.	Ash, &c.	Poles, bavins, cord-wood, &c.
Chalky, flinty gravelly loam.	Chalk, with some gravelly loam.	Ditto.	Ditto.	Ditto.
Gravelly loam.	Heavy, flinty, and poor loam.	Oak, ash, hazel, and beech.	Ash, oak, &c.	Common produce a few poles, cord-wood, bavins, &c. Plantation many poles, and the above.
Gravelly and chalky loams.	Gravelly loam with chalk.	Oak, ash, &c.	Ash and chefnut.	Poles, cord-wood, &c.
Gravelly loam.	Ditto.	Ash, oak, and beech.	Oak, larch.	Ditto.
Ditto.	Gravelly loam and heavy loam.	Ditto.	Scotch pine.	Ditto.
Sandy gravel.	Gravelly and sandy loam.	Ash, oak, beech, and Scotch pine.	Larch, chefnut, &c.	Poles, stakes, ethers, &c.
Stone shatter and gravelly loam.	Strong loam with ragstone.	Oak, hazel, birch, &c.	Birch, oak, &c.	Oaken tillers, small timber poles, &c.
	Gravelly loam with some stone.	Oak, birch, aspen, hazel, and ash.	Ash, chefnut, and willow.	Fencing-poles, hop-poles, cord-wood, &c.
Gravelly loam.	Gravelly loam, with some stones.	Oak.	Chefnuts.	Hop-poles, fence-poles, &c.
Sandy loam.	Gravelly loam.	Birch, oak, hornbeam, &c.	Chefnut, &c.	Fence-poles, hop-poles, &c.
Sandy loam and stone shatter.	Gravelly loam with ragstone.	Oak, beech, birch, hazel, ash.	Ditto.	Ditto.
Gravelly loam and stone shatter.	Deep loam, heavy clay and gravel.	Ditto.	Ditto.	Ditto.
Ditto.	Gravelly loam.	Ditto.	Ditto.	Ditto.
Gravelly and sandy loam.	With strong clay and loam.	Oak and ditto.	Ash, larch, &c.	Poles, fire-wood, &c. as above.
Gravelly loam flinty.	Gravel with clay and some flint.	Scrubby oak, hazel, &c.	Oak, ash.	Timber and ditto.
Wet spungy land.	Moist and boggy earth.	Alder, willow.	Alder, osier, willow, &c.	Hurdles, hop-poles, &c.
Drier ditto.	Ditto more dry.	Poplar.	White poplar, willow.	Hop-poles, &c.
Light sandy loam.	Dry gravelly earth.	Mountain ash, ash.	Scotch pine, silver fir.	Hop-poles.
Light gravelly loam.	With dry gravel.	Ash.	Sycamore.	Timber, turnery, &c.

PLANTING.

Mr. Nicol states, that in planting, where it is performed on the more elevated or mountainous tracts, warmth and shelter are to be considered, as without these the trees seldom thrive in a perfect manner. In such situations there is, in general, the most difficulty and the least progress made in the raising of timber trees; the success of the planter depending greatly upon fixing or such sorts of timber trees as may in future become the most highly valuable, on planting thickly with plants of not too large a size, and on a considerable plot, or extent of ground both in length and width being planted. In these unfriendly situations to the growth of trees, small plants must consequently be chosen and planted thick on the ground; as the winds are very prejudicial to trees of a large stature, by loosening the roots, and frequently breaking the fibres; but though this is the most disadvantageous situation for planting, it is possible, with proper care in the above respects, to rear young timber in it. Where it is intended to cover a mountain from its base, it will be most conveniently done by planting round the base in the first instance, rising gradually; by which means an artificial shelter will be forming, from the progress that will be made by the trees that were first planted, especially if the extent is such as to require several seasons to complete the planting. The portion first planted should be pretty extensive, in all such cases especially where shelter is principally intended.

The kinds of trees to be chosen for such situations must be regulated, in a great measure, by the soil. The pine would perhaps be found to flourish most, but the larch is preferable as a nursery. The mountain-ash, the beech, the ash, the sycamore, the birch, the fir, &c. may all be planted with reasonable hope of success; and where the soil is deepest and richest the oak. But in low sheltered situations, where the inconvenience of exposure to the winds is obviated, timber-trees may be planted with greater certainty of success; the chief care necessary in this case being to fix on trees of a proper kind, and placing them at proper distances, according to their sorts and sizes. As these situations admit of most kinds, on the more sheltered parts, the oak, larch, elm, beech, horse-chestnut, walnut, lime, spruce, and silver fir may be suitable; and on the less sheltered portions, the ash, birch, sycamore, hornbeam, mountain-ash, and fir, with a mixture of larch. It may likewise be noticed that the banks of rivers and canals are mostly favourable for the planter's purpose, and most sorts of timber and other woods may be raised in such situations; the oak, elm, poplar, willow and osier, according as they are more or less dry; but the preference must depend on the local circumstances of the different cases.

But in situations near the sea-coast, as they are in general inimical to the growth of timber, the beech and sycamore will be mostly found the most proper, as bearing the sea air better than other sorts. At least they are of great use in nursing the other sorts of trees till they acquire sufficient strength. It is advised in such places, as the best mode of performing the business, to plant, where the banks rise high, in the face of them much within the level of the tops, in order to afford a screen for the trees within till they have attained a sufficient height; but when they are flat, to have recourse to planting in belts, commencing the work as close to the edge of the water as possible, putting the plants in, in a very thick manner in the first rows, as at the distances of not more than about thirty inches, and using such plants as are stout, well rooted, and not more than eighteen inches growth.

Raising the Plants.—The different methods of providing the plants have been already noticed under the head of

PLANTATION; but the most useful are either by raising them in nurseries near the spot to be planted till of proper sizes, or by purchasing them from nurserymen in the neighbourhood. For extensive tracts of ground the first is the most advantageous mode, but when only small tracts are to be covered, the latter may often be the most advisable. In forming the nursery grounds, great attention should be paid to having them properly situated in respect to warmth, and the soil well broken down and enriched by proper manures. In Nottinghamshire, in the duke of Portland's extensive plantations, a well situated and sheltered valley, as contiguous as possible, is fixed upon for the purpose, and a space of ground sufficient for the purpose is well fenced in; large boarded gates being placed at each end, with a road down the middle proper for admitting carriages to convey away the young trees. When after the fence is completed the ground on each side the road is trenched about twenty inches deep, which may be done for about 3*l.* 10*s.* or 4*l.* per acre, according as the land is more or less gravelly. It is best done in the spring, when the planting season is over. If, after the trenching, two or three chaldron of lime be laid on an acre, the land will produce an excellent crop either of cabbages or turnips, which being eaten off by sheep in the autumn, will make the land in fine order for all sorts of tree seeds: but as the oak is the sort of tree cultivated in general, this is the method pursued in raising and managing that most valuable species. In the autumn, after the cabbages or turnips are eaten off, the ground requires nothing more than common digging. As soon as the acorns fall, after being provided with a good quantity, sow them in the following manner: draw drills with a hoe in the same manner as is practised for peas, and sow the acorns therein so thick as nearly to touch each other, and leave the space of one foot between row and row, and between every fifth row the space of two feet for the alleys. While the acorns are in the ground, great care must be taken to keep them from vermin, which would very often make great havoc amongst the beds, if not timely prevented. Let this caution serve for most other sorts of tree seeds.

As soon as the acorns are come up, the beds require only to be kept clean from weeds till they want thinning; and as the plants frequently grow more in one wet season, where the soil is tolerably good, than in two dry ones, where the soil is indifferent, the time for doing this is best ascertained by observing when the tops of the rows meet, which is done when that is the case by taking away one row on each side the middlemost, which leaves the remaining three rows the same distance apart as the breadth of the alleys. In taking up these rows, the workman ought to be careful neither to injure the plants removed, nor those left on each side. The rest of the young oaks being now left in rows at two feet apart, let them again stand till their tops meet, then take up every other row, and leave the rest in rows four feet asunder, till they arrive to the height of about five feet; which is full as large a size as is ever wished to be planted. In taking up the two last sizes, the method is to dig a trench at the end of each row, full two feet deep, then undermine the plants, and let them fall into the trench with their roots entire; as very much of their future success depends on this point of their being well taken up. And a similar mode is necessary with other sorts of trees in providing them for the purpose of planting.

But in the place of this method, the acorns as well as other seeds of trees are sometimes sown at first where they are to grow and remain. This method, the author of the Argyleshire Report says, makes the best timber; the plants suffer no checks, nor feel the inconvenience of a change of soil,

PLANTING.

foil, and the expence of raising an extensive plantation in this manner is very trifling. Besides, it is found that these seeds of trees will grow in situations in which the plants have failed. The most expeditious way of sowing the seed in this manner, is, by a party of three men working together. The first with a paring spade takes up a turf, the second stirs the earth with a spade, and the third distributes the seed and covers it. If any of the seedlings fail, they may be replaced by young plants raised on a similar foil, which will soon be reconciled, when very young, to their change of situation. Indeed the oak, when planted from the seed, or at most from the seed-bed, adapts itself wonderfully to almost any foil or situation; though it delights most in that which is very dry and gravelly.

In many cases, after the plants have been kept in the feminary or seed-bed for about two years, they are removed to a nursery of this kind, and planted in rows or lines twelve or more inches apart according to their sort, and from three to five in the rows, where they remain for two years longer, and are then finally planted out.

Preparation.—As soon as the plants have been raised in some of these methods, so as to be in a state for planting out, the next point to be attended to, where the ground has been properly drained, is that of preparing it for their reception. In this business great care is necessary, as much depends upon its being in a good condition for the reception of the plants. It is performed by the plough or the spade according to the different circumstances of the land. When coarse plants prevail, such as heath, furze, broom, &c. they must be fully destroyed by stubbing them up, burning, or otherwise clearing them away. When burning is practised, the ashes should be blended with the foil, as they are found of great service in promoting the growth of the plants; in the opinion of Mr. Nicol. But the mode of preparing by the plough on tillable scites, where the foil is thin, is the cheapest and most effectual of any; as where the land has been in tillage, it wants nothing more than two furrows and an equal number of harrowings, to render it fit for the reception of the trees. But where it is in lay, a crop of oats, &c. should be taken the season before planting; or if it is stubborn, a second crop, perhaps of beans, turnips or potatoes, will be necessary; previously ploughing and harrowing well, and laying the land up in a perfect method. A trench plough is frequently used for this purpose, which stirs the ground to twelve or thirteen inches. In this method it is essential to plough to the full depth each time, in order that the roots of the plants may strike down more freely into the foil.

Where the spade is employed, which must be the case in steep situations where the plough cannot come, and where there are rock, stones, or other obstructions; the best planters advise, that the holes or pits should be made to the full depth of the foil, and sufficiently large according to the size of the trees. For those of eighteen or twenty inches in height, whose roots occupy about nine inches when spread out, holes of fifteen inches in diameter may be sufficient. This must, however, be regulated by the judgment of the planter. And as it is of great advantage to the trees that the turfy matter should be well broken down and reduced before the time of planting, it may be useful to have the holes made a proper length of time before the trees are put in, to admit of this being fully effected, especially on the drier and more light soils, where there is a smaller proportion of this material.

Mr. Nicol states, that from the desire of early appearance it has been too much the case to plant forest-trees of too great growth. It is, however, found, that there is not only

much saving of expence, but a much greater certainty of success, in planting small young trees than such as are large and of greater age. Such as have been in the nursery two, three, or four years according to their kind, may in common be the most advantageous as timber trees. He also thinks that deciduous trees of all kinds, except the larch, of from three to five feet in height, being carefully raised with good roots, will generally succeed. He has, however, shewn, that a one year's seedling larch, nursed one or at most two years, will outdo all others of its kind in any foil or situation, and therefore advises planting trees of this age only. Firs of any kind will succeed better if under than above thirty inches, even in the most favourable foil and situation. Most generally those of fifteen or eighteen inches in height are to be preferred. From this view of the subject, it may occur to some, that to plant seedlings only would be the most adviseable and least expensive method. That it would be the least expensive method is obvious; but, that it is most adviseable, except for the Scotch and spruce firs, may, he thinks, be disputed.

As the chief property of any young tree intended for transplantation, consists in a multiplicity of healthy fibres; hence the necessity of nursing, in kindly foil, for a year or two, all tap-rooted plants, for the attainment of this object, and that we may commit them to the less genial foil and more untoward situation with greater probability of success. For, whether shall we suppose the plant which has both root and branch to make, or that which has the latter only, in the first season after so important a change of habit, is more likely to succeed?—the latter, certainly. From which alone may be demonstrated the cause why plants of this description surpass those of greater size, as stated above. These are raised with unbroken, tufty, and fibry roots; those with maimed, lank, fibreless ones; nor do they, with the utmost skill and attention, bear such proportion to the top. Consequently the fibrils cannot afterwards, by the utmost efforts of human art, be induced so immediately to seek pasturage for the sustentance of the trunk. For though lopping may in a great measure obviate this, injury is thereby done to the tree. In all soils and situations it is the safest and least expensive method to plant young healthy well rooted plants, where they can be procured.

Distances, Manner, and Time of Planting.—Mr. Nicol's directions are, that for the most exposed, bleak scites, and barren foil, from thirty to forty inches may be considered as a good medium; varying according to circumstances. For in an extensive tract, it will hardly happen that there is not a variety of soils. Some parts may be deeper and more loamy; others more gravelly and rocky. In the former, the greater distance may be adviseable; in the latter the lesser. But for less exposed scites, and where foil is found above six inches in depth, from four to five feet will be a good medium; varying the distances according to circumstances as above. And for belts, stripes, or clumps, whose breadth or diameter does not exceed a hundred feet, lying in a bleak situation, and thin foil, the margin, on all sides, should be planted at not more than two feet apart: the interior at three. Those lying on a more sheltered situation, and of deeper foil, may be allowed distance according to circumstances. But narrow stripes, or small clumps, even if the foil may be termed good, should generally be planted thicker than a more extended mass, that the plants may afford each other shelter.

For the more sheltered scites, where the foil is deep, good, and where apparently every plant will grow, six feet will be a good medium distance. Wider than this he cannot approve in any case whatever; because at this distance, the

PLANTING.

plants have room to grow till their thinnings become useful. But even where this is not an object, there is a greater; namely, that the plants may not grow too squat in their infancy, and that the pruning hook be not much wanted in the formation of stately timber. It is supposed that he who plants too thin, with the idea of saving trouble in thinning, deviates as widely from the right path, as he who thins none at all. It is, therefore, contended that thick, rather than thin planting, is the safer side to err on. By which mode also, there is a more equal crop on the ground, beeting or filling up vacancies being much less necessary. And in opposition to the common practice, it is supposed that thick planting is most necessary where the plants are largest, as the greatest number die in these cases. The Nottinghamshire Report states, that in the duke of Portland's plantations, where trees of various sizes are planted in an irregular manner, the number upon an acre is usually about two thousand; but in other cases the number is frequently much larger.

With respect to the manner of setting the trees in the plantations, it is probably the best method, except where vegetable crops are to be cultivated between, to plant without any regular order, though the line or row manner is frequently practised, as being the least troublesome and expensive of any that can be adopted. With respect to the most advantageous manner of blending or intermixing the trees, it is observed that some have advised the planting in groups, to prevent the supposed injury of trees of different sorts growing together; others, however, prefer the mixed method, not only as affording a better means of ascertaining what sorts of timber trees succeed best, but as enabling the planter to protect them more effectually. It has, however, been suggested by Mr. Nicol, that it matters little whether we plant in distinct groups or in indiscriminate mixture; provided, in the latter case, we ultimately retain the most profitable and flourishing kinds only: for, with the proviso that most of the kinds evidently adapted to the soil and situation be planted according to the mode of thick planting, a sufficiency of them will remain, after all others are thinned away, for a full and final crop. For instance: if it should be supposed that the soil is best adapted to the oak; that it is desirable to raise the most valuable kinds rather than the decorative; and that, exclusive of the larch for nurseries, and a few firs to enliven the borders, six kinds are to compose the mixture; plant two oaks for one elm, two elms for one beech, two beeches for one ash, two ashes for one birch, and two birches for one sycamore. And thus will the plantation at once be formed, in uniform gradation, of kinds most likely to succeed each other, in the case of either disagreeing with the soil or climate; and which also succeed each other in respect of value as timber: doing justice, at least, to the patriotic intention of the planter, should the first and more valuable kinds fail.

It is conceived that in all situations, and on all soils, except those termed humid, and which are adapted to the aquatic kinds only, the larch is, without doubt, the most proper nurse, and therefore should take preference of all others for this purpose. But on sub-humid, or loamy soils, the Lombardy poplar and Huntingdon willow are good substitutes; and, when variety is the object, ought to be mixed with the larch, for the purpose of nursing the other more valuable kinds. And that on elevated, poor scites, the mountain-ash, for the first ten or fifteen years, is outdone by the larch only in the office of nursing, and is justly admitted for the sake of variety. In all situations, this plant grows quickly in youth. In maritime situations, the sycamore is likewise evidently useful for this purpose. Few

trees, except the above, grow faster in youth; and none are more patient of the sea-breeze. Consequently, when the scite is much exposed thereto, this tree should be freely planted in mixture with the larch for nursing the oak, beech, elm, &c. if the intention be the culture of ship-timber. It is likewise suggested, that the common pine may sometimes be useful in this view, and afford greater variety. The proportion in which trees of this sort should be employed, must necessarily depend on the peculiarity of the situation, and other circumstances. Some recommend in thin soils, and bleak situations, tree for tree; and in less exposed situations, and better soils, one nurse for two principal trees; and in most sheltered situations, with good soil, one nurse for three, four or five principal trees may be a sufficient allowance. On the most exposed and bleak situations, where the soil is evidently sterile, the safest way is to plant too many rather than too few, as, unless well sheltered, the timber trees never succeed well in exposed situations.

The time of planting these sorts of trees with the most advantage, and the greatest chance of success, differs according to the nature of the soils and the plants, as well as in the state of the weather. It has been stated, that in the more porous dry soils, with the hardier sorts of trees, the autumn, as from the middle of October to the latter end of November, may be the most suitable; as they will be better established against the summer heats, which are often destructive to new planted trees. But in the more heavy soils, especially those of the clayey and loamy kinds, and with less hardy sorts of trees, the early spring season, as from the middle or latter end of February to the beginning of April, may be the most proper. The condition of the land should be particularly attended to in this sort of work, as it is equally improper to plant when either in too dry or too moist a situation. At a time when the soil is neither wet nor dry, the operation of planting is most easily, and also most successfully performed. The mould adheres not to the spade, nor does it run in; it divides well, and with little trouble intermingles with the fibres; nor, in the operation of treading and setting the plant upright, is it wrought into a mortar, to the evident prejudice of the plant, whatever weather may ensue. Consequently, on a retentive soil, it cannot be proper to plant in time of rain, nor in many cases for a day or two afterwards; nor after a fall of snow, until for several days it has entirely disappeared. Whereas on a dry absorbent soil, it may be very proper to plant in time of gentle rains or immediately after heavy ones.

Another circumstance which ought to be regarded in this business, is the difference in the forwardness of the vegetation of different sorts of trees, as it should regulate in some degree the time of planting, where those of the same sorts are only made use of. In this view, it is advised that the larch, elm, sycamore, lime, horse-chestnut, mountain-ash, birch, alder, poplar, willow, and some others, should be put in by the beginning of March; and that the oak, birch, ash, chestnut, hornbeam, &c. be finished planting by the beginning of April at the latest. The best season for planting of many trees of the evergreen kind, such as the Weymouth pine, spruce, Scotch, silver, and other firs, is supposed by some to be in the latter end of July, or in the beginning of the following month, when the weather is inclined to be moist or cloudy.

Planting out.—It is advised, that as soon as the trees have been taken up with care, so as to injure the fibres of the roots as little as possible, and a few of the bruised extremities cut off, they should, when intended to be planted in mixture, be put together in proper proportions, and conveyed in this

PLANTING.

way to the place where they are to be planted. They must then be distributed on the ground, at the pits or other places, in order to be ready for the planters, as by this means much time is saved, which would otherwise be lost in forting. But to prevent the roots from getting too dry, it is necessary not to take up or bring on to the land more than can be planted in a short space of time. But where only one or two sorts of trees are to be planted, the usual practice of carrying the plants along as the planting proceeds, may be the most convenient method for performing the work. And the operation is the best and most readily performed by two persons: a man to do the work, and a boy to hold the plants. In executing the work, the labourer first stirs the mould well in the holes or pits that have been previously prepared, rendering it level, and fit for the reception of the plant: or forms new holes according to the mode of planting that is adopted. The boy then places the plant in the hole, with all the fibres of its roots regularly spread out and unconfined, to the depth of about an inch more than it had stood in the nursery, holding it perfectly upright; while the man gently fills in the loose mould, moving the tree a little up and down to let it mix with the roots: the remainder of the earth is afterwards put in; and the labourer proceeds to the preparation of the next hole, leaving the boy to set the plant erect and close the mould about it, which in soils of the stiffer sorts should be only performed in a light manner, but in those of the drier kinds, as the sandy and gravelly, as closely as possible. In this way the work is to proceed till the whole is finished. There are other methods of planting sometimes made use of, such as by forming slits, nicks, or openings of other kinds, so as just to press in the roots of the plants; but these, from the roots being confined, and having no loose fresh mould to shoot into, seldom answer in any perfect manner. It is well remarked that much of the success of the planter depends upon this part of the work being well executed; but that great care should be taken, particularly where the land is inclined to moisture, or of a retentive quality, not to plant at too great a depth. In planting on steep, it is directed that the trees should be placed towards the declivity, being put in at the lowest part of the opening; which should, in completing the work, be left the highest, by which the moisture may be better preserved for the support of the plant.

It seems not improbable, the author of Practical Agriculture says, but that in many cases and situations, the planting of small trees of the timber kind might be performed with great convenience and expedition by the assistance of a plough suitable for the purpose, as has been sometimes practised in setting hedge-plants. Where trees of considerable growth are planted, great attention is necessary to have them well secured against the wind, as, when they become loose, the fibres are so broken and destroyed that they soon die. This has been commonly effected by means of staking: but as in this way the trees are often in danger of being injured by rubbing, a practice of ramming the earth closely about the roots has been attempted, which in some soils, and upon small scales of planting, has, it is said, been found to succeed; but in extensive concerns it is wholly inadmissible, from the trouble that must attend it.

When the plants have been all put in, it is a practice in some cases to sow or set the plantations with acorns, as it is found that sown oaks as well as other trees exceed in growth those that are planted. This work is done either by paring off the surface with a mattock, and setting the acorns with a dibble, or by putting them in slight drills by the hoe, at the distance of about six inches. The best season for performing this business is in April, and it may be performed

the first, second, or third year after planting the ground, but the first or second is probably to be preferred. It is advised that great care should be taken to preserve the acorns well, by exposure to the air and frequent turning, as they are very apt to sprout soon after being gathered. The proportions of these and other sorts of seeds that are necessary are thus stated in the Nottingham Agricultural Report.

Quantities per Acre.

- Of acorns from four to six strikes.
- ash keys, four strikes.
- Spanish chestnuts, one ditto.
- hawthorn berries, one ditto.

It is necessary to bury the ash keys and hawthorn berries one year in beds or pots of sand before they are sown in these situations.

When the trees have been thus planted out, it is advised as necessary not to lose sight of them, as the young plants should be kept clean and free from the annoyance and choaking of coarse weeds of all kinds, for at least three or four years. This may be done by the hoe in many cases; but some have recourse to the culture of different sorts of crops in this view. In this method, however, much care is requisite not only to avoid injuring the plants, but to guard against the soil being too much impoverished, and their growth thereby retarded in too great a degree. And where coarse plants abound, such as broom, furze, briars, and other similar productions, in all the less exposed situations, they should be wholly cut up and destroyed; but in bleak exposures it may be a better practice to only clear them to a distance round the trees, so that they cannot do any injury by rubbing or striking against them, the others being left for the purpose of sheltering and protecting the young trees during their young growth. There is another circumstance likewise to be attended to in this business, which is that of filling up the vacancies that are caused by the dead plants. Where the ground is kept perfectly clean, this may be done at any proper season; but in other cases, when the dead plants cannot be so easily detected, it may be better to delay the business to the third or fourth year, when the deficiencies can be more perfectly ascertained. If this sort of business be done too early, many plants are frequently removed that would have thrown out from the bottom, on account of their not being dead in that part, though wholly gone in the top. It is advised that the plants employed in filling up these vacancies should never be too large, as where that is the case they are liable to die or be destroyed.

There is still another kind of planting which is frequently practised, but the propriety of which is not yet well ascertained. It is that of setting hedge-rows with trees of the timber kinds. The utility of the practice is maintained by some on the ground of the degree of shelter and ornament that it affords, and its being a means of raising much useful timber at little or no expence; while others condemn it as highly improper, and disadvantageous, on the principle that much injury is not only done to the crops, especially when of the grain kind, by the dropping and the spreading of the roots, but also to the hedge in the places where they stand, by their producing gaps and openings. The author of a late practical work, however, suggests, that though some inconvenience and injury may be sustained where this sort of planting is much in use in arable districts; yet from these being, in a great measure, capable of being obviated by proper training and pruning, and from the naked appearance which is exhibited without them in a country, but more particularly from the vast benefit that may be derived

derived in the way of timber; it would seem that some extent of planting in this method should be attempted in most situations. Mr. Middleton hints, that it would not be an easy matter to make an accurate estimate of the advantages to be derived from such a measure: but in order to gain a slight idea as to the quantity of hedge-row timber, let it be considered that, in well-enclosed, hedged, and cultivated districts, the hedge-rows occupy from a twentieth to a tenth of the whole surface. Even including the common fields, and cultivated slopes and borders of sheep-downs, the average quantity of land occupied by hedge-rows, at this time, amounts to a twentieth, or two millions of acres; all of which might probably be made to produce timber: more than half of it, however, would no doubt do so, by only trimming the lowest side branches off to the height of ten, twelve, or fifteen feet from the ground. This would permit the air to circulate freely, give every advantage to the occupier's crops; and would leave sufficient tops upon the trees for the purposes of growth and rural ornament. Under management like this, the hedges would every where present healthy, vigorously-growing, and handsome timber; and would add very much to the profit of the land owner, to the security of the country, and to the pleasures of the traveller. But in performing the work of planting in such cases, the nature of the land, the sort of husbandry that it is principally conducted under, and the kind of exposure in which it is placed, should be well considered, and the sort of trees properly adapted to it. In dry soils, most sorts of timber trees, as has been seen, may be planted; but in those more stiff and heavy kinds, the oak and the elm may be the most proper. The ash should, perhaps, never be had recourse to where the land is almost wholly under the plough; but on lands under the grazing or grass system, it may be planted with advantage. In bleak and exposed situations, the beech is probably the best for this use; and near the sea the sycamore. The trees where the ground is mostly in an arable state should be planted at much greater distances than under the contrary circumstances, and such trees as run most to tall clear stems be preferred. It is recommended that the young trees in this sort of planting should be larger than in other cases, being kept in the nursery two years longer than has been here advised, and shifted so as to produce more fibrous roots. When about five or six feet in height they are probably in the most suitable condition for being planted out in these places.

In these cases the most proper time of planting in hedge-rows is, when the fields are first broken up from the state of lay, as at that time, from their being continued in the state of tillage for some years, there will be less trouble and expence in protecting them from cattle by palings, &c. as well as less danger of their being injured by the browsing of live stock, as they will be advanced beyond their reach by the time the land is restored to grass.

Where the planting is performed in the hedge-rows of grass lands, the trees must always be perfectly secured from the croppings of cattle, as well as the rubbing of sheep, or other animals, as where this is not the case, they are soon much injured, and frequently wholly destroyed. The work of planting in these cases should be carefully performed in the manner described; and where the trees do not stand perfectly firm against the wind, be well secured by stakes, or other proper means, as they never thrive well when not kept perfectly fast and steady in the soil.

The practice frequently employed of converting the hedge-row timber trees into pollards by lopping off their

top branches, should constantly be guarded against as much as possible, as it is the destruction of timber. Where pollards abound, they are mostly cropped once in from about nine to fifteen years, the profits of which, in general, belong to the tenant. This work should be constantly finished by the end of February, where it is in use, at the latest.

As soon as the trees have acquired a tolerable growth, it is necessary, in all cases, to attend to the proper pruning and thinning of them occasionally as they advance, in order to prevent their growing in an improper manner, and their injuring each other by rubbing or being drawn up weak. In the first intention, they are therefore to be occasionally looked over after the third season from planting, and such headed down, or otherwise cut, as may appear necessary for their more regular or perfect growth. When this has been done, the only thing further will be to encourage a leader, by shortening all the other branches that appear to contend with it to nearly one-third of their length, in order to strengthen their main stem. The whole that is afterwards necessary, is that of properly thinning the strong top branches, and those on the sides, which may be done by a light bill. This is, however, only applicable to trees of the forest kind; those of the fir and evergreen sort require nothing more than the regulation of their leaders, as that of keeping them single where they throw out double. The less the side branches are touched the better in all these sorts of trees, as they are very much hurt by cutting.

On the whole, planting is without doubt the most productive improvement that can be attempted on poor barren lands, and ought to be promoted in every way as much as possible; but more especially by the application of some sort of stimulus which could have the effect of inducing the proprietors of lands, in situations proper for it, not to neglect such undertakings, as being the best means of rendering their properties fully and completely valuable, as well as of benefiting the country.

PLANTING, Inverse or Reverse, is a method of planting, in which the ordinary position of the plant, or shoot, is inverted; the branches being set in the earth, and the roots reared into the air.

Agricola mentions this monstrous way of planting, which, he assures us, succeeds very well in most, or all sorts of fruit-trees, timber-trees, &c. both foreign and domestic. Bradley affirms his having seen a lime-tree in Holland, growing with its first roots in the air, which had shot out branches in great plenty, at the same time that its first branches were turned into roots, and fed the tree.

The industrious Mr. Fairchild has practised the same with us, and gives us the following directions for the performance of it.

Choose a young tree of one shoot, of alder, elm, willow, or any other tree that takes root readily by laying; bend the shoot gently down, till the extreme part be in the earth, and so let it remain till it has taken good root. This done, dig about the first root, and gently take it up out of the ground, and raise it till the stem be nearly upright; in which state stake it up.

Then prune the roots, now erected in the air, from the bruises and wounds they received in being dug up; and anoint the pruned parts with a composition of four parts of bees'-wax, four of tallow, two of resin, and two of turpentine, melted together, and applied pretty warm. Then prune off all the buds or shoots upon the stem, and dress the wounds with the same composition, to prevent any collateral shootings; and leave the rest to nature.

PLANTING, in *Architecture*, denotes the laying the first courses

courses of stone on the foundation, according to the measures, with all the exactness possible.

PLANTS, in *Botany* and *Vegetable Physiology*, compose the second of the three kingdoms of nature. To define the limits of these, the animal, the vegetable, and the fossil kingdoms, has exercised the ingenuity of philosophers. When fossils were believed to possess a vegetative power, which even Tournefort maintained, the chief difficulty lay in distinguishing them from plants; but since the mineral kingdom has been ascertained to depend on the laws of chemistry alone, all ambiguity on that side of the question is removed. On the other hand, in proportion as the physiology of plants has been studied, their anatomy, nutrition, development, and propagation, have been found so nearly allied to similar functions in animal bodies, that increase of knowledge has but augmented our perplexity. The following are among the most approved definitions, intended to discriminate between animals, vegetables, and fossils.

Jungius, in his *Isagoge*, p. 1, says "a plant is a living body destitute of sensation; or it is a body attached to some certain place or seat, whence it derives powers of nourishment, increase, and propagation." Linnæus cites this passage inaccurately in *Phil. Bot.* 1. He observes, in a manuscript note, that the floating sea-weeds, and *Conservez*, form an exception.

Boerhaave considers a plant as "an organic body, attached by some part of itself to some other body, whence it derives nourishment."

Ludwig asserts that "natural bodies constantly endowed with the same form, and with locomotion, are animals; those which have the same form, without locomotion, are vegetables; and those which have a diversity of form, are minerals." To this Linnæus well objects, the perfect regularity of form in crystals of the same species; and the want of locomotion in several animals.

Tournefort, in his *Isagoge*, 54, says "a plant is an organic body, always furnished with roots, perhaps always with seeds, and almost always with leaves, flowers, and stems."

Allston has defined vegetables as nourished by pores situated in their external surface, animals by vessels in their internal one.

Linnæus, in *Phil. Bot.* 1, has given the most neat, and generally approved, definition. "Stones grow. Vegetables grow and live. Animals grow, live, and feel."—To which he has subjoined, in manuscript, "*et se movent, motu possibili*;" *i. e.* and are endowed with a certain degree of spontaneous motion.

Difficulties attend all these positions. The want of sensation in vegetables cannot be demonstrated, nor are appearances to the contrary wanting; so that it can never serve for a practical mode of discrimination, nor as a basis for any philosophical argument.

Mirbel, in his *Traité d'Anatomie et de Physiologie Végétales*, has remarked "that plants alone have a power of deriving nourishment, though not indeed exclusively, from inorganic matter, mere earths, salts or airs, substances certainly incapable of serving as food for any animals, the latter only feeding on what is or has been organized matter, either of a vegetable or animal nature. So that it should seem to be the office of vegetable life alone to transform dead matter into organized living bodies."

To this we can find no exception. However inconvenient, and indeed impossible to be used, as a practical test, it appears to be a sound philosophical distinction, between the animal and vegetable kingdoms. The fossil or mineral

kingdom is essentially distinguished from both, by the want of an organized structure, developed and increased by absorption; and of a vital principle, essential to the performance of all the functions on which their health, growth and propagation depend.

Plants come under consideration, in various points of view, in a work like the present. For what concerns their anatomy and physiology, see ANATOMY, BARK, CORTEX, CIRCULATION of Sap, FECUNDATION of Plants, LEAF, FLOWER, GERMEN, PERICARP, &c.: for their scientific arrangement and discrimination, see BOTANY, CLASSIFICATION, FLORA, FIGURES of Plants, GENUS, SPECIES, NATURAL Orders, SYSTEM, &c. See also LICHENES and MUSCI. The reader is requested to correct two typographical errors in the latter article, column eighth, line 18 from the top, for *sinks* read *sbrinks*; and line eight from the bottom, for *sexual* read *esexual*.

PLANTS of Britain, the natural spontaneous production of our soil and climate, have formed the subject of many separate botanical works. More or less perfect catalogues of British plants have been published by How, Ray, Petiver, Willson, Hill, Jenkinson, and others, besides a number of local Floras. Ray's *Synopsis Methodica Stirpium Britannicarum* first set the example of a systematic arrangement, and scientific discrimination, of our native vegetable productions, and has been the foundation of all that has been done since. This excellent work was accommodated to the Linnæan system and principles, with augmentations, by Hudson, and has led the way to the labours of Withering, Lightfoot, Robson, Broughton, Wade, Hull, Curtis, Relhan, Abbott, and the writer of the present article, whose *Flora Britannica*, extended as yet no farther than the end of the *Musci*, was written on a comparison of all that had before been done, with the specimens of the Linnæan herbarium. This Latin work has been followed up and illustrated by the figures, and English descriptions, of the same author's *English Botany*, drawn, engraved, and published by Mr. Sowerby, which is just now come to a conclusion, in thirty-six volumes octavo, with 2592 coloured plates. In the progress of this latter work, since the *Flora Britannica*, or the *Compendium Fl. Britannica*, appeared, about 150 species have been added to the British list; even in the first twenty-three, or phænogamic, classes of the Linnæan system. We propose, therefore, in the present article, to exhibit a complete catalogue of the Phænogamic plants of Britain, as far as the present state of our knowledge extends, with a reference throughout to the *English Botany*, in which, with two or three exceptions only, they are now all separately delineated. These amount to 1450. So full an enumeration of British plants has no where, hitherto, appeared; and we shall take the opportunity of correcting mistakes of the *Flora Britannica*, respecting certain species erroneously there admitted. This catalogue is arranged according to the Linnæan system, with those slight alterations only, which are adopted in the *Fl. Brit.* and accounted for in the author's *Introduction to Botany*. Each plant is mentioned by its generic and specific names, in Latin and English; then follows a reference to the volume and plate of *Engl. Bot.*—The particular situation, duration, and flowering month, of every species are subjoined. Whatever the reader may wish further to know, is to be sought under the name of each genus, at its proper place in the alphabet. New species, not there mentioned, are particularly described or defined, and various necessary corrections are given respecting preceding articles, as in the classes *Tetradynamia* and *Gynandria*. New matter, regarding genera

PLANTS.

nera belonging to the posterior part of the alphabet, will hereafter be found there. An asterisk (*) is prefixed to every species, presumed to be of foreign origin, or but imperfectly naturalized here; and a cross (†) to those concerning which some error is suspected, they being, not at present, found in the places indicated, and perhaps having had other species originally mistaken for them. The Latin names throughout correspond with the *Flora Britannica* and *English Botany*, except where the contrary is expressed by a synonym between crotchets.

The 24th class, *Cryptogamia*, though not omitted, is necessarily treated in the most compendious manner, it being impracticable at present correctly to enumerate the British species of that class. Even a partial catalogue of them would also have extended this article too far. They are nearly all, except *Fungi*, included in the *English Botany*.

Class I. MONANDRIA.

Ord. I. Monogynia.

SALICORNIA. Glasswort.

1. *S. herbacea*, common, or samphire. vol. 6. pl. 415. Sandy sea shore. Annual. 8th and 9th months.
2. *S. procumbens*, procumbent. 35. 2475. Sea shore. Ann. 8.
3. *S. radicans*, creeping. 24. 1691. Muddy shores. Perennial. 9.
4. *S. fruticososa*, shrubby. 35. 2467. Sea-coast, rare. Per. 8, 9.

HIPPURIS. Mare's-tail.

1. *H. vulgaris*, common. 11. 763. Pools and ditches. Per. 5.

CHARA. Chara.

1. *C. vulgaris*, common. 5. 336. Muddy waters. Ann. 7.
2. *C. hispida*, prickly. 7. 463. Pools and ditches. Ann. 7, 8.
3. *C. flexilis*, smooth. 15. 1070. Pools and lakes. Ann. 7, 8.
4. *C. translucens*, great transparent. 26. 1855. Pools, rare. Ann. 6, 7.

This is the larger plant of Vaillant, fig. 8, mentioned as a variety of *flexilis* in our article CHARA, n. 4.

5. *C. nidifica*, proliferous. 24. 1703. Sea ditches. Ann. 7, 8.

"Smooth, transparent, without prickles. Leaves cylindrical, elongated, all simple. Anther often stalked."

More slender and branched than the last, but more stout and firm in habit than *C. flexilis*.

6. *C. gracilis*, slender. 30. 2140. Pools, rare. Ann. 9.

"Smooth, transparent, shining, without prickles. Lateral branches repeatedly forked; their segments awl-shaped, acute. Leaves awl-shaped, often branched."

Much smaller and more tufted than the last. When dry almost colourless, shining like glass.

ZOSTERA. Grass-wrack.

1. *Z. marina*, sea. 7. 467. Sea ditches. Per. 8, 9.

Ord. 2. Digynia.

CALLITRICHE. Water Star-leaf.

1. *C. aquatica*, common. 11. 722. Ditches and pools. Ann. 4—10.

Class 2. DIANDRIA.

Ord. 1. Monogynia.

LIGUSTRUM. Privet.

1. *L. vulgare*, common. 11. 764. Woods and hedges. Shrubby. 5, 6.

FRAXINUS. Ash.

1. *F. excelsior*, common. 24. 1692. Woods and hedges. Tree. 4, 5.
2. *F. heterophylla*, simple-leaved. 35. 2476. Woods, rare. Tree. 4, 5.

See FRAXINUS, n. 8. var. b.—Vahl's name, *heterophylla*, is preferable to *simplicifolia*, as a few leaves are often ternate, or even pinnate, on the same tree with the simple ones.

CIRCÆA. Enchanter's Nightshade.

1. *C. lutetiana*, common. 15. 1056. Shady dank places. Per. 6, 7.
2. *C. alpina*, mountain. 15. 1057. Rocks and woods. Per. 7, 8.

VERONICA. Speedwell.

1. *V. spicata*, spiked. 1. 2. Chalky pastures. Per. 7—9.
2. *V. hybrida*, Welch. 10. 673. Mountains, rare. Per. 7.
3. *V. officinalis*, male, or common. 11. 765. Barren heaths. Per. 5, 6.
4. *V. saxatilis*, blue rock. 15. 1027. Highlands. Per. 7.
5. *V. fruticulosa*, flesh-coloured shrubby. 15. 1028. Highl. Per. 7.
6. *V. alpina*, alpine. 7. 484. Highland rills. Per. 7, 8.
7. *V. serpyllifolia*, smooth. 15. 1075. Meadows and pastures. Per. 5, 6.
8. *V. Beccabunga*, brooklime. 10. 655. Rivulets. Per. 7.
9. *V. Anagallis*, water. 11. 781. Rivers and ditches. Per. 7.
10. *V. scutellata*, narrow marsh. 11. 782. Sandy ditches. Per. 7, 8.
11. *V. montana*, mountain. 11. 766. Chalky woods. Per. 5, 6.
12. *V. Chamædrys*, germander. 9. 623. Groves and hedges. Per. 5.
13. *V. agrestis*, procumbent. 11. 783. Fields and gardens. Ann. 4—9.
14. *V. arvensis*, wall. 11. 734. Dry ground. Ann. 5.
15. *V.hederifolia*, ivy-leaved. 11. 784. Fields, &c. Ann. 4, 5.
16. *V. triphyllus*, fingered. 1. 26. Sandy fields, rare. Ann. 4.
17. *V. verna*, vernal. 1. 25. Barren fields. Ann. 4.

PINGUICULA. Butterwort.

1. *P. lusitanica*, pale. 3. 145. Bogs, rare. Per. 6, 7.
2. *P. vulgaris*, common. 1. 70. Bogs. Per. 5, 6.
3. *P. grandiflora*, large-flowered. 31. 2184. Bogs, Ireland. Per. 5, 6.

UTRICULARIA. Bladder-wort.

1. *U. vulgaris*, common. 4. 253. Ditches and pools. Per. 7.
2. *U. intermedia*, intermediate. 35. 2489. Lakes, Irel. Per. 7.
3. *U. minor*, lesser. 4. 254. Bogs and ditches. Per. 7.

LEMNA. Duck-weed.

1. *L. trisulca*, ivy-leaved. 13. 926. Pools and ditches. Ann. 6.

2. *L.*

PLANTS.

2. *L. minor*, lesser. 16. 1095. Pools, common. Ann. 6, 7.
 3. *L. gibba*, gibbous. 18. 1233. Pools. Ann. 6, 7.
 4. *L. polyrrhiza*, greater. 35. 2458. Ditches. Ann. 7, 8?
- Flowers of this species only have never been observed.

LYCOPUS. Water-horehound.

1. *L. europæus*, common. 16. 1105. Ditches. Per. 7, 8.

SALVIA. Clary.

1. *S. pratensis*, meadow. 3. 153. Dry meadows, rare. Per. 7.
2. *S. verbenaca*, common English. 3. 154. Pastures. Per. 6—10.

Ord. 2. *Digynia*.

ANTHOXANTHUM. Vernal-grafs.

1. *A. odoratum*, sweet-scented. 9. 647. Pastures. Per. 5.

Class 3. TRIANDRIA.

Ord. 1. *Monogynia*.

VALERIANA. Valerian.

1. *V. rubra*, red. 22. 1531. Walls, and chalk cliffs. Per. 6—9.
2. *V. dioica*, small marsh. 9. 628. Marshes. Per. 6.
3. *V. officinalis*, great wild. 10. 698. Marshes and hills. Per. 6.
4. *V. pyrenaica*, heart-leaved. 23. 1591. Woods, Scotland. Per. 6.
5. *V. Locusta*, corn-fallad. 12. 811. Fields, common. Ann. 4.
6. *V. dentata*, oval-fruited. 20. 1370. Fields, rare. Ann. 6, 7.

CROCUS. Saffron.

- *1. *C. fativus*, cultivated. 5. 343. Fields. Per. 9.
2. *C. vernus*, spring. 5. 344. Meadows and pastures. Per. 3.
3. *C. nudiflorus*, naked-flowering. 7. 491. Sandy low meadows. Per. 10.

IXIA. Ixia.

1. *I. Bulbocodium*, Dwarf. 36. 2549. Hillocks, Jersey. Per. 4.

IRIS. Iris.

1. *I. Pseud-acorus*, yellow. 9. 578. Waters. Per. 7.
2. *I. fatidissima*, stinking. 9. 596. Groves. Per. 6.

SCHOENUS. Bog-rush.

1. *S. Mariscus*, prickly. 14. 950. Bogs and marshes. Per. 7, 8.
2. *S. nigricans*, black. 16. 1121. Spongy turf bogs. Per. 6.
3. *S. compressus*, compressed. 11. 791. Spongy meadows. Per. 7.
4. *S. rufus*, red-brown. 15. 1010. Marshes. Per. 7.
5. *S. albus*, white-headed. 14. 985. Spongy bogs. Per. 8.

Stamens but two. Seeds with many bristles at the base.

6. *S. fuscus*, brown-headed. 22. 1575. Bogs, South Wales. Per. 8.

Stamens three. Seeds with only three bristles at the base.

CYPERUS. English Galangale.

1. *C. longus*, sweet-scented. 19. 1309. Marshes, rare. Per. 7.

SCIRPUS. Club-rush.

1. *S. palustris*, marsh creeping. 2. 131. Bogs and ditches. Per. 6, 7.
2. *S. multicaulis*, many-stalked. 17. 1187. Turfy bogs. Per. 7.
3. *S. cespitosus*, scaly-stalked. 15. 1029. Turfy heaths. Per. 7.
4. *S. pauciflorus*, chocolate-headed. 16. 1122. Mountain bogs. Per. 8.
5. *S. acicularis*, leaf. 11. 749. Moist heaths. Per. 8.
6. *S. fluitans*, floating. 3. 216. Ditches and pools. Per. 7, 8.
7. *S. lacustris*, bull-rush. 10. 666. Clear waters. Per. 7.
8. *S. glaucus*, glaucous. 33. 2321. Salt marshes. Per. 7, 8.
9. *S. Holoschoenus*, round cluster-headed. 23. 1612. Seashore. Per. 8—11.
10. *S. setaceus*, brittle-stalked. 24. 1693. Sandy wet places. Ann. 7, 8.
11. *S. triquetus*, triangular. 24. 1694. Marshes and rivers. Per. 8.
12. *S. carinatus*, blunt-edged. 28. 1983. Rivers. Per. 8.
13. *S. maritimus*, salt-marsh. 8. 542. Salt marshes. Per. 7, 8.
14. *S. sylvaticus*, wood, or millet. 13. 919. Moist woods. Per. 7.

ERIOPHORUM. Cotton-grafs.

1. *E. vaginatum*, hare's-tail. 13. 873. Highland moors. Per. 3, 4.
2. *E. capitatum*, round-headed. 34. 2387. Highland mountains. Per. 8.
3. *E. polytachion*, broad-leaved. 8. 563. Bogs. Per. 4.
4. *E. angustifolium*, narrow-leaved. 8. 564. Bogs. Per. 4.
5. *E. gracile*, slender mountain. 34. 2402. Highland mountains. Per. 7.
6. *E. alpinum*, alpine. 5. 311. Highland bogs. Per. 4, 5.

NARDUS. Mat-grafs.

1. *N. stricta*, common. 5. 290. Sandy moist heaths. Per. 7.

Ord. 2. *Digynia*.

PHALARIS. Canary-grafs.

- *1. *P. canariensis*, manured. 19. 1310. Waste ground. Ann. 6—8.
2. *P. arundinacea*, reed. 6. 402. 30. 2160. f. 2. Ditches, &c. Per. 7.

PANICUM. Panick-grafs.

1. *P. verticillatum*, rough. 13. 874. Moist fields. Ann. 6, 7.
2. *P. viride*, green. 13. 875. Sandy fields. Ann. 7.
3. *P. Crus-galli*, loose. 13. 876. Moist fields. Ann. 7.
4. *P. sanguinale*, cock's-foot. 12. 849. Fields, rare. Ann. 7.
5. *P. dactylon*, creeping. 12. 850. Sandy sea-shore. Per. 7, 8.

PHLEUM. Cat's-tail-grafs.

1. *P. pratense*, common. 15. 1076. Pastures. Per. 6—10.
2. *P.*

PLANTS.

2. *P. alpinum*, alpine. 8. 519. Highlands. Per. 7.
3. *P. paniculatum*, paniced. 15. 1077. Fields, rare. Ann. 7.
4. *P. Boehmeri*, canary. 7. 459. Sand or chalk. Per. 7.
5. *P. Michelii*, Michelian. 32. 2265. Highland rocks. Per. 7.
6. *P. arenarium*, fea. 4. 222. Sandy fields. Ann. 6.

ALOPECURUS. Fox-tail-grafs.

1. *A. pratensis*, meadow. 11. 759. Pastures and meadows. Per. 5.
2. *A. alpinus*, alpine. 16. 1126. Highlands. Per. 7.
"Stem erect, smooth. Spike ovate. Glumes of the calyx downy, without awns, and nearly as long as the awns of the corolla."—Found by the late Mr. G. Don on mountains about Loch Nagore, Aberdeenshire. *Stem* a foot high. *Spike* white and downy, scarcely an inch long.
3. *A. agrestis*, slender. 12. 848. Cornfields, and way sides. Ann. 7.
4. *A. bulbosus*, bulbous. 18. 1249. Salt marshes. Per. 7.
5. *A. geniculatus*, floating. 18. 1250. Ponds and ditches. Per. 7.
6. *A. fulvus*, orange-spiked. 21. 1467. Ponds. Per. 7.
"Stem ascending, bent at the joints. Spike compound, cylindrical. Glumes obtuse, hairy. Awn the length of the calyx. Anthers roundish."—Larger than the last. *Anthers* orange-coloured, opening at each side by an oval orifice.

KNAPPIA. Knappia.

1. *K. agrostidea*, early. 16. 1127. Sandy places, rare. Ann. 3, 4.

POLYPOGON. Beard-grafs.

1. *P. monspeliensis*, long-awned. 24. 1704. Salt marshes. Ann. 7, 8.
2. *P. littoralis*, short-awned. 18. 1251. Muddy salt marshes. Per. 8.

MILIUM. Millet-grafs.

1. *M. effusum*, spreading. 16. 1106. Moist woods. Per. 6, 7.
2. *M. lendigerum*, close, or panick. 16. 1107. Low fields. Ann. 8.

AGROSTIS. Bent-grafs.

1. *A. Spica venti*, silky. 14. 951. Moist fandy fields. Ann. 6, 7.
2. *A. canina*, brown. 26. 1856. Moist pastures. Per. 7.
3. *A. fetacea*, bristly. 17. 1188. Dry heaths. Per. 7, 8.
4. *A. vulgaris*, fine. 24. 1671. Pastures and heaths. Per. 7.
5. *A. stolonifera*, creeping. 22. 1532. Moist fields. Per. 7, 8.
6. *A. alba*, marsh. 17. 1189. Bogs and woods. Per. 7.

AIRA. Hair-grafs.

1. *A. cristata*, crested. 9. 648. Dry pastures. Per. 7, 8.
2. *A. aquatica*, water. 22. 1557. Ponds, &c. Per. 5, 6.
3. *A. capillosa*, turfy. 21. 1453. Moist ground. Per. 6, 7.
4. *A. lævigata*, smooth-sheathed. 30. 2102. Highlands, and sea-coast. Per. 5, 6.
"Leaves flat; with very smooth sheaths. Panicle close. Petals awned, hairy at the base. Partial stalk smooth and very short."—Native of Lapland as well as Scotland. Generally viviparous. Not half so tall as the last.
5. *A. flexuosa*, wavy. 22. 1519. Sandy heaths. Per. 7.

6. *A. canescens*, grey. 17. 1190. Sandy shores. Per. 7.
7. *A. præcox*, early. 18. 1296. Dry gravelly places. Ann. 5, 6.
8. *A. caryophyllæa*, silver. 12. 812. Barren heaths. Ann. 7.

HOLCUS. Soft-grafs.

1. *H. lanatus*, meadow. 17. 1169. Meadows and pastures. Per. 6, 7.
2. *H. mollis*, creeping. 17. 1170. Fields and woods. Per. 7, 8.
3. *H. avenaceus*, oat-like. 12. 813. Waste ground. Per. 6, 7.

MELICA. Melic-grafs.

1. *M. uniflora*, wood. 15. 1058. Groves. Per. 5, 6.
2. *M. nutans*, mountain. 15. 1059. Mountain woods. Per. 6, 7.
3. *M. cærulea*, purple. 11. 750. Wet fandy ground. Per. 8.

SESLERIA. Moor-grafs.

1. *S. cærulea*, blue. 23. 1613. Limestone rocks. Per. 4.

POA. Meadow-grafs.

1. *P. aquatica*, reed. 19. 1315. Ditches and rivers. Per. 7.
2. *P. fluitans*, flote. 22. 1520. Ponds and ditches. Per. 6—8.
3. *P. distans*, reflexed. 14. 986. Waste ground. Per. 7.
4. *P. maritima*, creeping fea. 16. 1140. Salt marshes. Per. 7.
5. *P. procumbens*, procumbent fea. 8. 532. Near the fea. Ann. 7, 8.
6. *P. rigida*, hard. 20. 1371. Walls. Ann. 6.
7. *P. compressa*, flat-stalked. 6. 365. Walls, &c. Per. 7, 8.
8. *P. alpina*, alpine. 14. 1003. Highlands. Per. 7.
9. *P. flexuosa*, zig-zag. 16. 1123. Highlands. Per. 7.
10. *P. bulbosa*, bulbous. 15. 1071. Sea-coast. Per. 5, 6.
11. *P. cæsia*, fea-green. 24. 1719. Highlands. Per. 6, 7.
12. *P. trivialis*, roughish. 15. 1072. Meadows and pastures. Per. 6—9.
13. *P. pratensis*, smooth-stalked. 15. 1073. Mead. and past. Per. 5, 6.
14. *P. humilis*, short blueish. 14. 1004. Mountain pastures. Per. 6.
15. *P. annua*, annual. 16. 1141. Cultivated ground. Ann. 3—11.
16. *P. glauca*, slender glaucous. 24. 1720. Mountains. Per. 6, 7.
17. *P. nemoralis*, wood. 18. 1265. Woods. Per. 6.
18. *P. decumbens*, decumbent. 11. 792. Barren bogs. Per. 7.

BRIZA. Quaking-grafs.

1. *B. minor*, small. 19. 1316. Fields, rare. Ann. 7.
2. *B. media*, common. 5. 340. Pastures. Per. 5, 6.

DACTYLIS. Cock's-foot-grafs.

1. *D. striata*, smooth. 6. 380. Muddy sea shore. Per. 8.
2. *D. glomerata*, rough. 5. 335. Meadows and pastures. Per. 6—8.

CYNOSURUS. Dog's-tail-grafs.

1. *C. cristatus*, crested. 5. 316. Pastures. Per. 7.
2. *C. echinatus*, rough. 19. 1333. Sandy ground. Ann. 7.

FESTUCA.

PLANTS.

FESTUCA. Fescue-grafs.

1. *F. ovina*, sheep's. 9. 585. Open pastures. Per. 6.
2. *F. vivipara*, viviparous. 19. 1355. Mountains. Per. 7.
3. *F. cæsia*, sea-green heath. 27. 1917. Dry heaths. Per. 6.

"Panicle pointing one way, clofe, glaucous. Florets cylindrical, roughifh, awned; inner glume rough-edged. Stem quadrangular. Leaves compressed, channelled, glaucous."—About Bury, Suffolk, forming broad, depressed, very glaucous tufts. *Stems* a span high.

4. *F. duriuscula*, hard. 7. 470. Meadows and pastures. Per. 6.
5. *F. rubra*, creeping. 29. 2056. Mountains and sea shore. Per. 7.
6. *F. bromoides*, barren. 20. 1411. Walls and fand. Ann. 6.
7. *F. myurus*, wall. 20. 1412. Walls and fand. Ann. 6.
8. *F. uniglumis*, fingle-hulked. 20. 1430. Sea fand. Ann. 6.
9. *F. triflora*, three-flowered. 27. 1918. Pastures. Per. 7.

"Panicle spreading. Spikelets three-flowered, with long awns."—Like the following, but lefs drooping, and with fewer florets.

10. *F. gigantea*, tall. 26. 1820. Woods and hedges. Per. 7, 8.
11. *F. calamaria*, reed-like. 14. 1005. Mountain woods. Per. 7.
12. *F. decidual*, deciduous. 32. 2266. Mountain woods. Per. 8.

"Panicle pointing one way, erect, much branched. Florets two or three, oblong, angular, beardless; the upper ones deciduous. Leaves linear, striated."—Lower and much more slender than the last. The lowermoft *floret* only ripens feed.

13. *F. loliacea*, spiked. 26. 1821. Moist pastures. Per. 6, 7.
14. *F. pratensis*, meadow. 23. 1592. Meadows and past. Per. 6, 7.
15. *F. elatior*, tall. 23. 1593. Moist meadows. Per. 6, 7.

BROMUS. Brome-grafs.

1. *B. secalinus*, fmooth rye. 17. 1171. Corn-fields. Ann. 7.
2. *B. multiflorus*, downy rye. 27. 1884. Corn-fields. Ann. 7.
3. *B. mollis*, foft. 15. 1078. Pastures, &c. Bienn. 6.
4. *B. racemosus*, fsmooth. 15. 1079. Past. and meadows. Ann. 6.
- †5. *B. squarrosus*, corn. 27. 1885. Corn-fields. Ann. 7.
6. *B. arvensis*, taper field. 28. 1984. Fields. Ann. 7.
7. *B. pratensis*, tumid field. 13. 920 (arvensis). Fields. Ann. 6.

"Panicle spreading, compound. Spikelets ovate, turgid, eight or ten-flowered. Florets elliptical, broad, imbricated, smoothifh, with three equidistant ribs at each fide."—Two feet high. *Panicle* fsmaller and more erect than in the last, but the *spikelets* are larger, more tumid, and greener. The true *arvensis* has only two clofe ribs on each fide the keel of the *glume*.

8. *B. erectus*, upright perennial. 7. 471. Chalky past. Per. 7.
9. *B. asper*, hairy wood. 17. 1172. Moist woods. Ann. Biennial. 7.
10. *B. sterilis*, barren. 15. 1030. Waste ground, and fields. Ann. 6, 7.

11. *B. diandrus*, upright annual. 14. 1006. Walls and fand. Ann. 6.
12. *B. sylvaticus*, slender wood. 11. 729. Thickets and hedges. Per. 7.
13. *B. pinnatus*, spiked heath. 11. 730. Chalky heaths. Per. 7.

STIPA. Feather-grafs.

- †1. *S. pennata*, plummy. 19. 1356. Rocks. Per. 7.

AVENA. Oat-grafs.

1. *A. fatua*, wild haver. 31. 2221. Fields. Ann. 8.
2. *A. strigosa*, bristle-pointed oat. 18. 1266. Corn-fields. Ann. 7.

This is now admitted as a native species, in consequence of its having been found in Scotland, Wales, Yorkshire, and Cornwall, notwithstanding the contrary opinion expressed in Fl. Brit. 140. See AVENA, n. 22.

3. *A. pubescens*, downy. 23. 1640. Chalky pastures. Per. 6.
4. *A. pratensis*, narrow leaved. 17. 1204. Limestone foil. Per. 7.
5. *A. planiculmis*, flat-strawed. 30. 2141. Highland mountains. Per. 7.

"Panicle erect. Calyx containing about five florets. Receptacles bearded upwards. Leaves naked, finely ferrated, with rough sheaths. Stem compressed."—Like *A. pubescens* in general aspect, but larger in every part, and the leaves are naked, not downy; their edges finely ferrated, as in *pratensis*. *Flowers* much larger than in either of thofe.

6. *A. flavescens*, yellow. 14. 952. Pastures and waste ground. Per. 6, 7.

LAGURUS. Hare's-tail-grafs.

1. *L. ovatus*, ovate. 19. 1334. Sands in Guernsey. Ann. 6.

ARUNDO. Reed.

1. *A. Phragmites*, common. 6. 401. Fens and ditches. Per. 7.
2. *A. epigejos*, wood. 6. 402. Moist woods. Per. 7.
3. *A. Calamagrostis*, fsmall. 30. 2159. Moist woods and fens. Per. 7.
4. *A. striata*, fsmaller clofe. 30. 2160. Marshes, Scotland. Per. 6.

"Calyx fingle-flowered, full as long as the corolla. *Panicle* erect, clofe. Flowers scattered, erect, with a dorsal awn. Down shorter than the corolla."—Half the fize of the last. *Calyx* acute, but without elongated points. *Stipula* very short. The *panicle* is of a purplifh bronze hue, not unlike *Melica cærulea*.

5. *A. arenaria*, sea. 8. 520. Sandy sea-coaft. Per. 7.

LOLIUM. Darnel.

1. *L. perenne*, perennial. 5. 315. Meadows and pastures. Per. 6.
2. *L. temulentum*, bearded. 16. 1124. Fields. Ann. 7.
3. *L. arvenfe*, white. 16. 1125. Fields, rare. Ann. 7.

ROTBOLLIA. Hard-grafs.

1. *R. incurvata*, sea. 11. 760. Salt marshes. Ann. 8.

ELYMUS. Lyme-grafs.

1. *E. arenarius*, upright sea. 24. 1672. Sandy sea-coaft. Per. 7.

2. *E.*

PLANTS.

2. *E. geniculatus*, pendulous fea. 23. 1586. Muddy fea-coaft. Per. 7.
3. *E. europæus*, wood. 19. 1317. Chalky woods. Per. 6.

HORDEUM. Barley.

1. *H. murinum*, wall, or moufe. 28. 1971. Way fides. Ann. 6—8.
2. *H. pratense*, meadow. 6. 409. Moist pastures. Per. 6.
3. *H. maritimum*, fea. 17. 1205. Salt marfhes. Ann. 6, 7.

TRITICUM. Wheat-grafs.

1. *T. junceum*, rufhy. 12. 814. Sandy coafts. Per. 7.
 2. *T. repens*, creeping, or couch. 13. 909. Walte ground. Per. 6—9.
 3. *T. caninum*, bearded. 20. 1372. Chalky woods. Per. 7.
 4. *T. cristatum*, crested. 32. 2267. Sea cliffs, Scotland. Per. 7?
- Bromus cristatus* of Linnæus; fee BROMUS, n. 32.
5. *T. loliaceum*, dwarf fea. 4. 221. Sea fand. Ann. 6, 7.

Ord. 3. Trigynia.

MONTIA. Blinks.

1. *M. fontana*, water. 17. 1206. Rills and fprings. Ann. 4, 5.

HOLOSTEUM. Jagged-chickweed.

1. *H. umbellatum*, umbelliferous. 1. 27. Old walls. Ann. 4.

POLYCARPON. All-feed.

1. *P. tetraphyllum*, four-leaved. 15. 1031. Sandy fouth coaft. Ann. 5—8.

Clafs 4. TETRANDRIA.

Ord. 1. Monogynia.

DIPSACUS. Teafel.

- *1. *D. fullonum*, manured. 29. 2080. Hedges. Bienn. 7.
2. *D. sylvestris*, wild. 15. 1032. Moist hedges. Bienn. 7.
3. *D. pilofus*, fmall. 13. 877. Moist chalks. Per. 8.

SCABIOSA. Scabious.

1. *S. succisa*, devil's bit. 13. 878. Pastures. Per. 8—10.
2. *S. arvensis*, field. 10. 659. Corn-fields. Per. 7.
3. *S. columbaria*, fmall. 19. 1311. Gravel or chalk. Per. 6, 7.

SHERARDIA. Field-madder.

1. *S. arvensis*, blue. 13. 891. Corn-fields. Ann. 5—8.

ASPERULA. Wood-ruff.

1. *A. odorata*, fweet. 11. 755. Woods. Per. 5.
2. *A. cynanchica*, fmall. 1. 33. Chalky hills. Per. 6.

GALIAM. Bed-ftraw.

1. *G. cruciatum*, cros-leaved. 2. 143. Thickets and hedges. Per. 5.
2. *G. palustre*, white water. 26. 1857. Moist meadows. Per. 7.
3. *G. Witheringii*, rough heath. 31. 2206. Moist hills. Per. 7.

VOL. XXVII.

4. *G. faxatile*, fsmooth heath. 12. 815. Heaths and dry hills. Per. 7, 8.

5. *G. uliginofum*, rough marfh. 28. 1972. Ditches. Per. 8.

6. *G. æreum*, upright. 29. 2067. Moist pastures. Per. 6, 7.

7. *G. verrucofum*, warty-fruited. 31. 2173. Corn-fields. Ann. 6—8.

This is the *Valantia Aparine* of Linnæus, whose feeds, be-
fet with large tubercles, are compared by Tournefort and
Vaillant to coriander comfits.

8. *G. tricornis*, three-flowered. 23. 1641. Corn-fields. Ann. 7.

9. *G. spurium*, fsmooth-seeded corn. 26. 1871. Corn-
fields, rare. Ann. 6, 7.

10. *G. pufillum*, leaf mountain. 2. 74. Limestone hills. Per. 7, 8.

11. *G. verum*, yellow. 10. 660. Fields and hills. Per. 7, 8.

12. *G. Mollugo*, great hedge. 24. 1673. Hedges. Per. 7, 8.

13. *G. anglicum*, wall. 6. 384. Old walls. Ann. 6, 7.

14. *G. boreale*, cros-leaved. 2. 105. Rocky hills. Per. 7.

15. *G. Aparine*, goofe-grafs. 12. 816. Hedges, common. Ann. 5—8.

RUBIA. Madder.

1. *R. peregrina*, wild. 12. 851. Rocks in the fouth. Per. 6, 7.

EXACUM. Gentianella.

1. *E. filiforme*, leaf. 4. 235. Sandy marfhes. Ann. 7.

PLANTAGO. Plantain.

1. *P. major*, greater. 22. 1558. Pastures and cultivated ground. Per. 5—9.

2. *P. media*, hoary. 22. 1559. Chalky hills. Per. 5—8.

3. *P. lanceolata*, rib-wort. 8. 507. Meadows and pa-
tures. Per. 6, 7.

4. *P. maritima*, fea. 3. 175. Sea-coaft and lofty moun-
tains. Per. 8.

5. *P. Coronopus*, buck's-horn. 13. 892. Sandy pastures. Ann. 5—8.

CENTUNCULUS. Chaff-weed.

1. *C. minimus*, fmall. 8. 531. Inundated heaths. Ann. 6, 7.

SANGUISORBA. Burnet.

1. *S. officinalis*, great. 19. 1312. Meadows and pastures. Per. 6.

EPIMEDIUM. Barren-wort.

1. *E. alpinum*, alpine. 7. 438. Mountain thicket, rare. Per. 5.

CORNUS. Cornel.

1. *C. fanguinea*, wild. 4. 249. Hedges. Shrub. 6.
2. *C. Suecica*, dwarf. 5. 310. Alpine meadows. Per. 6, 7.

PARIETARIA. Pellitory.

1. *P. officinalis*, wall. 13. 879. Old walls. Per. 6—9.

ALCHEMILLA. Ladies'-mantle.

1. *A. vulgaris*, common. 9. 597. Meadows and pa-
tures. Per. 6, 7.

2. *A. alpina*, alpine. 4. 244. Micaceous rocks. Per. 7.

PLANTS.

3. *A. arvensis*, field. 15. 1011. Fallow fields. Ann. 5—8.
 Ord. 2. *Digynia*.
 BUFFONIA. *Buffonia*.
 †1. *B. tenuifolia*, slender. 19. 1313. Sea-coast? Ann. 6.

Ord. 3. *Tetragynia*.
 ILEX. *Holly*.

1. *I. Aquifolium*, common. 7. 496. Woods and hedges. Tree. 5.

POTAMOGETON. Pond-weed.

1. *P. natans*, broad-leaved. 26. 1822. Ponds and rivers. Per. 7.
 2. *P. heterophyllum*, various-leaved. 18. 1285. Ditches and pools. Per. 7—9.
 3. *P. perfoliatum*, perfoliate. 3. 168. Rivers and pools. Per. 7, 8.
 4. *P. densum*, close-leaved. 6. 297. Pools and slow streams. Per. 6.
 5. *P. fluitans*, long-leaved floating. 18. 1286. Ditches and rivulets. Per. 8, 9.
 6. *P. lucens*, shining. 6. 376. Rivers, pools and lakes. Per. 6, 7.
 7. *P. lanceolatum*, lanceolate. 28. 1985. Lakes, Wales. Per. 8.
 8. *P. crispum*, curled. 15. 1012. Pools and rivers. Per. 6, 7.
 9. *P. compressum*, flat-stalked. 6. 418. Rivers and ditches. Per. 6, 7.
 10. *P. gramineum*, grassy. 32. 2253. Rivers and ditches. Per. 7.
 11. *P. pufillum*, small. 3. 215. Clay-pits. Per. 7.
 12. *P. pedunculatum*, fennel-leaved. 5. 323. Rivers and marine ditches. Per. 7.

RUPPIA. Ruppia.

1. *R. maritima*, sea. 2. 136. Salt-water ditches. Per? 7.

SAGINA. Pearl-wort.

1. *S. procumbens*, procumbent. 13. 880. Sandy wastes. Per. 5—8.
 2. *S. maritima*, sea. 31. 2195. Sea-coast, and mountains. Ann. 5—8.
 3. *S. apetala*, small-flowered. 13. 881. Sandy wastes. Ann. 5, 6.
 4. *S. erecta*, upright. 9. 609. Gravelly pastures. Ann. 5.

TILLÆA. Tillæa.

1. *T. muscosa*, mossy. 2. 116. Sandy heaths. Ann. 5, 6.

RADIOLA. Flax-feed.

1. *R. millegrana*, thyme-leaved. 13. 893. Wet sand. Ann. 7, 8.

Class 5. PENTANDRIA.

Ord. 1. *Monogynia*.

MYOSOTIS. Scorpion-grass.

1. *M. arvensis*, field. 36. 2558. Dry fields. Ann. 6.
 "Seeds smooth. Leaves oblong. Branches spreading.

Clusters many-flowered, without bractæas; their lower stalks axillary and remote. Calyx ovate, with spreading incurved bristles."—See MYOSOTIS, n. 1; where the author, Mr. Drake, has mentioned two varieties. The β is our following species, *versicolor*; the γ is also probably distinct, but has not yet been published as such in Engl. Bot.

2. *M. versicolor*, yellow and blue. 7. 480. f. 1. Barren fields. Ann. 6.

"Seeds smooth. Leaves oblong. Branches ascending. Clusters many-flowered, on long naked stalks, without bractæas. Calyx ovate, with spreading incurved bristles."—Found sometimes also in boggy meadows. The flowers are yellow when they first open.

3. *M. palustris*, water. 28. 1973. Ditches and pools. Per. 7, 8.

4. *M. rupicola*, rock. 36. 2559. Highland rocks. Per. 7.
 "Seeds smooth. Leaves oblong; the radical ones on long footstalks. Clusters many-flowered, without bractæas. Calyx divided above half way down, its hairs copious, spreading and elongated."—Most like the last; with still larger blue flowers.

LITHOSPERMUM. Gromwell.

1. *L. officinale*, common. 2. 134. Chalky hills. Per. 5.
 2. *L. arvense*, corn. 2. 123. Fields. Ann. 5, 6.
 3. *L. purpuro-ceruleum*, creeping. 2. 117. Chalky thickets, rare. Per. 5.

ANCHUSA. Alkanet.

1. *A. officinalis*, common. 11. 662. Rubbish by the sea. Per. 6, 7.
 2. *A. sempervirens*, evergreen. 1. 45. Waste ground. rare. Per. 5, 6.

CYNOGLOSSUM. Hound's-tongue.

1. *C. officinale*, common. 13. 921. Waste ground. Bienn. 6.
 2. *C. sylvaticum*, green-leaved. 23. 1642. Shady hedges. Bienn. 6.

PULMONARIA. Lung-wort.

1. *P. officinalis*, common. 2. 118. Groves, rare. Per. 5.
 2. *P. angustifolia*, narrow-leaved. 23. 1628. Groves, rare. Per. 5.
 3. *P. maritima*, sea. 6. 368. Sandy shores. Per. 7.

SYMPHYTUM. Comfrey.

1. *S. officinale*, common. 12. 817. Watery places. Per. 5, 6.
 2. *S. tuberosum*, tuberous-rooted. 21. 1502. Moist groves. Per. 7.

BORAGO. Borage.

1. *B. officinalis*, common. 1. 36. Waste ground. Bienn. 6, 7.

ASPERUGO. Madwort.

1. *A. procumbens*, procumbent. 10. 661. Waste ground, rare. Ann. 5.

LYCOPSIS. Buglofs.

1. *L. arvensis*, small. 14. 938. Fields and hedges. Ann. 6, 7.

ECHUM.

PLANTS.

ECHIUM. Viper's-buglofs.

1. *E. italicum*, white. 29. 2081. Sandy fields, rare. Bienn. 7.
2. *E. vulgare*, common blue. 3. 181. Fields and walls. Bienn. 6, 7.

PRIMULA. Primrose.

1. *P. vulgaris*, common. 1. 4. Groves and banks. Per. 4.
2. *P. elatior*, ox-lip. 8. 513. Groves, rare. Per. 4.
3. *P. veris*, cowslip. 1. 5. Meadows and pastures. Per. 4, 5.
4. *P. farinosa*, bird's-eye. 1. 6. Mountain bogs. Per. 6, 7.

CYCLAMEN. Cyclamen.

- *1. *C. europæum*, spring. 8. 548. Groves, rare. Per. 4.

MENYANTHES. Buck-bean.

1. *M. trifoliata*, common. 7. 495. Wet meadows. Per. 6, 7.
2. *M. nymphæoides*, fringed. 4. 217. Rivers. Per. 8.

HOTTONIA. Water-violet.

1. *H. palustris*, common. 6. 364. Pools and ditches. Per. 6, 7.

LYSIMACHIA. Loofsefrife.

1. *L. vulgaris*, yellow. 11. 761. Watery thickets. Per. 7.
2. *L. thyrsiflora*, tufted. 3. 176. Bogs, rare. Per. 7.
3. *L. nemorum*, wood. 8. 527. Groves. Per. 5-9.
4. *L. Nummularia*, creeping. 8. 528. Shady rills. Per. 6, 7.

ANAGALLIS. Pimpernel.

1. *A. arvensis*, scarlet. 8. 529. Fields and gardens. Ann. 6, 7.
2. *A. carulea*, blue. 26. 1823. Fields, rare. Ann. 6, 7.
3. *A. tenella*, bog. 8. 530. Bogs and springs. Per. 7, 8.

AZALEA. Azalea.

1. *A. procumbens*, trailing. 13. 865. Alpine heaths. Small shrub. 7.

CONVOLVULUS. Bind-weed.

1. *C. arvensis*, small. 5. 312. Gravelly pastures. Per. 6, 7.
2. *C. sepium*, great. 5. 313. Moist hedges. Per. 7, 8.
3. *C. Soldanella*, sea. 5. 314. Sandy sea-coast. Per. 7.

POLEMONIUM. Jacob's-ladder.

1. *P. caruleum*, blue. 1. 14. Mountain thickets, rare. Per. 6.

CAMPANULA. Bell-flower.

1. *C. rotundifolia*, round-leaved. 13. 866. Heaths and banks. Per. 8, 9.
2. *C. patula*, spreading. 1. 42. Pastures, rare. Bienn. 7, 8.
3. *C. Rapunculus*, rampion. 4. 283. Banks. Bienn. 7, 8.
4. *C. latifolia*, giant. 5. 302. Woods and shady rocks. Per. 8.
5. *C. rapunculoides*, creeping. 20. 1369. Woods, rare. Per. 8.

6. *C. Trachelium*, nettle-leaved. 1. 12. Groves and hedges. Per. 7.
7. *C. glomerata*, clustered. 2. 90. Chalky hills. Per. 7, 8.
8. *C. hybrida*, corn. 6. 375. Chalky fields. Ann. 8.
9. *C.hederacea*, ivy-leaved. 2. 73. Shady rills, rare. Per. 6-8.

PHYTEUMA. Rampion.

1. *P. orbiculare*, round-headed. 2. 142. Chalky hills, rare. Per. 8.

JASIONE. Sheep's-bit.

1. *J. montana*, scabious. 13. 882. Sandy pastures. Ann. 6, 7.

LOBELIA. Lobelia.

1. *L. Dortmanna*, water. 2. 140. Lakes, rare. Per. 7.
2. *L. urens*, acrid. 14. 953. Moist heaths, rare. Per. 8, 9.

IMPATIENS. Balfam.

1. *I. Noli-me-tangere*, yellow. 14. 937. Shady springs, rare. Ann. 8.

VIOLA. Violet.

1. *V. hirta*, hairy. 13. 894. Limestone woods. Per. 4.
2. *V. odorata*, sweet. 9. 619. Groves and banks. Per. 3, 4.
3. *V. palyfris*, marsh. 7. 444. Mossy bogs. Per. 4.
4. *V. canina*, dog's. 9. 620. Groves and heaths. Per. 4-6.
5. *V. lactea*, cream-coloured. 7. 445. Mountainous heaths. Per. 5.
6. *V. tricolor*, common pansy. 18. 1287. Fields. Ann. 5-9.
7. *V. lutea*, yellow mountain. 11. 721. Mountain bogs. Per. 5-9.

VERBASCUM. Mullein.

1. *V. Thapsus*, great. 8. 549. Hedges and way sides. Bienn. 7, 8.
2. *V. Lychnitis*, white. 1. 58. Chalky banks. Bienn. 7, 8.
3. *V. pulverulentum*, yellow hoary. 7. 487. Gravelly banks. Bienn. 7.
4. *V. nigrum*, dark, or black. 1. 59. Gravel or chalk. Per. 7, 8.
5. *V. virgatum*, large-flowered. 8. 550. Gravelly fields, rare. Bienn. 8.
6. *V. Blattaria*, moth. 6. 393. Gravelly fields. Ann. 7.

DATURA. Thorn-apple.

- *1. *D. Stramonium*, prickly. 18. 1288. Dunghills and waives. Ann. 7.

HYOSCYAMUS. Hen-bane.

1. *H. niger*, common. 9. 591. Waste ground. Ann. 7.

ATROPA. Deadly-nightshade.

1. *A. Belladonna*, common, or dwale. 9. 592. Chalky hills. Per. 6.

SOLANUM. Nightshade.

1. *S. Dulcamara*, woody. 8. 565. Hedges. Shrub. 6, 7.
2. *S. nigrum*, common, or garden. 8. 566. Cultivated ground. Ann. 6-9.

PLANTS.

CHIRONIA. Centaury.

1. *C. Centaurium*, common. 6. 417. Gravelly pastures. Ann. 7, 8.
2. *C. littoralis*, dwarf tufted. 33. 2305. Sea-coast. Ann. 6.
"Stems herbaceous, simple, straight. Leaves linear-ovate. Calyx-teeth awl-shaped. Flowers densely cymbose, nearly sessile."—About two inches high. Flowers large and handsome. Distinct from the varieties of the foregoing mentioned under CHIRONIA, n. 11.
3. *C. pulchella*, dwarf branched. 7. 458. Sandy sea-coast. Ann. 8, 9.

SAMOLUS. Brook-weed.

1. *S. Valerandi*, pimpernel. 10. 703. Marshes. Per. 7.

LONICERA. Honeyfuckle.

1. *L. Caprifolium*, pale perfoliate. 12. 799. Groves and coppices. Shrub. 5, 6.
2. *L. Periclymenum*, common woodbine. 12. 800. Woods and hedges. Shrub. 6, 7.
3. *L. Xylosteum*, upright. 13. 916. Thickets, rare. Shrub. 7.

RHAMNUS. Buckthorn.

1. *R. catharticus*, common. 23. 1629. Hedges. Shrub. 5, 6.
2. *R. Frangula*, alder-leaved. 4. 250. Woods and thickets. Shrub. 5.

EUONYMUS. Spindle-tree.

1. *E. europæus*, common. 6. 362. Hedges and woods. Shrub. 5.

RIBES. Currant.

1. *R. rubrum*, red. 18. 1289. Shady banks of northern rivers. Shrub. 5.
2. *R. alpinum*, tasteless mountain. 10. 704. Woods and thickets. Shrub. 4, 5.
3. *R. spicatum*, acid mountain. 18. 1290. Mountain woods. Shrub. 5.
4. *R. petraeum*, rock. 10. 705. Mountains. Shrub. 5.
5. *R. nigrum*, black. 18. 1291. Wet thickets. Shrub. 5.
- *6. *R. Grossularia*, rough gooseberry. 18. 1292. Hedges. Shrub. 4.
- *7. *R. Uva crispa*, smooth gooseberry. 29. 2057. Hedges. Shrub. 4.

HEDERA. Ivy.

1. *H. Helix*, common. 18. 1267. Woods and walls. Shrub. 10.

ILLIPEBERRUM. Knot-weed.

1. *I. verticillatum*, whorled. 13. 895. Sea marshes, Dev. and Corn. Per. 7.

GLAUX. Salt-weed.

1. *G. maritima*, sea, or black. 1. 13. Muddy salt-marshes. Per. 6, 7.

THESIUM. Bastard Toad-flax.

1. *T. linophyllum*, common. 4. 247. Chalky hills. Per. 7.

VINCA. Periwinkle.

1. *V. minor*, lesser. 13. 917. Banks and groves. Per. 5.
2. *V. major*, greater. 8. 514. Woods and hedges. Per. 5.

Ord. 2. Digynia.

HERNIARIA. Rupture-wort.

1. *H. glabra*, smooth. 3. 206. Sand or gravel. Per. 7, 8.
2. *H. hirsuta*, hairy. 20. 1379. Sand, rare. Per. 7, 8.

CHENOPODIUM. Goosefoot.

1. *C. Bonus Hénricus*, perennial. 15. 1033. Waste ground. Per. 5, 6.
2. *C. urbicum*, upright. 10. 717. Dunghills and banks. Ann. 8, 9.
3. *C. rubrum*, red. 24. 1721. Waste ground. Ann. 8.
4. *C. botryodes*, many-clustered. 32. 2247. Sea marshes. Ann. 8.

"Leaves triangular, somewhat toothed; the upper ones bluntish. Clusters upright, compound, rounded, leafy." Leaves much smaller, and more fleshy, than in the last, of which it has long been taken for a maritime variety.

5. *C. murale*, nettle-leaved. 24. 1722. Walls and banks. Ann. 8, 9.
6. *C. hybridum*, maple-leaved. 27. 1919. Moist waste ground. Ann. 8.
7. *C. album*, white. 24. 1723. Fields and gardens, common. Ann. 7, 8.
8. *C. ficifolium*, fig-leaved. 24. 1724. Dunghills and fields. Ann. 8.
9. *C. glaucum*, oak-leaved. 21. 1454. Sandy fields. Ann. 8.
10. *C. olidum*, stinking. 15. 1034. Near the sea. Ann. 8.
11. *C. polyspermum*, round-leaved. 21. 1480. Dunghills, &c. Ann. 7, 8.
12. *C. acutifolium*, sharp entire-leaved. 21. 1481. Waste ground. Ann. 7, 8.

"Leaves ovate, acute, entire. Stem erect. Clusters somewhat cymose, elongated, leafless."—Differs from the last, with which it has generally been confounded, in its erect, more angular stem, and sharp-pointed leaves. The clusters also are spiked rather than cymose.

BETA. Beet.

1. *B. maritima*, sea. 4. 285. Muddy sea-shores. Per. 8.

SALSOLA. Salt-wort.

1. *S. Kali*, prickly. 9. 634. Sandy beach. Ann. 7.
2. *S. fruticososa*, shrubby. 9. 635. Norfolk and southern coasts. Shrub. 7, 8.

ULMUS. Elm.

1. *U. campestris*, common, or Norfolk. 27. 1886. Woods and hedges. Tree. 4.
2. *U. suberosa*, cork-barked, or Suffex. 31. 2161. Woods and hedges. Tree. 3.
3. *U. glabra*, smooth, or wych. 32. 2248. Hedges, Effex. Tree. 3.
4. *U. montana*, broad-leaved, or wych hazel. 27. 1887. Woods and hedges. Tree. 4.
- *5. *U. major*, Dutch. 36. 2542. Hedges. Tree. 3.

CUSCUTA. Dodder.

1. *C. europæa*, greater. 6. 378. On thistles and nettles. Ann. 8, 9.
2. *C. Epithymum*, lesser. 1. 55. On heath and thyme. Per? 8.

SWERTIA.

PLANTS.

SWERTIA. Felwort.

- †1. *S. perennis*, marsh. 21. 1441. Alpine bogs. Per. 8.

GENTIANA. Gentian.

1. *G. Pneumonanthe*, marsh. 1. 20. Moist heaths. Per. 8, 9.
2. *G. acaulis*, dwarf. 23. 1594. South Wales. Per. 5.
3. *G. verna*, spring. 7. 493. Barren mountains. Per. 4.
4. *G. nivalis*, small alpine. 13. 896. Highland rocks. Ann. 8.
5. *G. Amarella*, autumnal. 4. 236. Limestone pastures. Ann. 8.
6. *G. campestris*, field. 4. 237. Gravelly pastures. Ann. 9.

Umbelliferous plants.

ERYNGIUM. Eryngo.

1. *E. maritimum*, sea. 10. 718. Sandy beach. Per. 7, 8.
2. *E. campestre*, field. 1. 57. Waste ground, rare. Per. 7, 8.

HYDROCOTYLE. White-rot.

1. *H. vulgaris*, marsh. 11. 751. Watery ground. Per. 5, 6.
2. *H. inundata*, floating. 4. 227. Ditches and pools. Bienn? 5.

SANICULA. Sanicle.

1. *S. europæa*, wood. 2. 98. Groves. Per. 5.

BUPLEURUM. Hare's-ear.

1. *B. rotundifolium*, round-leaved. 2. 99. Chalky fields. Ann. 7.
2. *B. odontites*, narrow-leaved. 35. 2468. Rocks, Devon. Ann. 7.
3. *B. tenuissimum*, slender. 7. 478. Muddy salt-marshes. Ann. 7, 8.

ECHINOPHORA. Prickly-Sampire.

- †1. *E. spinosa*, great. 34. 2413. Sandy sea-coast. Per. 7.

TORDYLIUM. Hart-wort.

- †1. *T. officinale*, smaller. 34. 2440. Fields, rare. Ann. 6, 7.
2. *T. maximum*, great. 17. 1173. Chalky ground, rare. Ann. 6, 7.

CAUCALIS. Bur-parsley.

1. *C. daucoides*, small. 3. 197. Chalky fields. Ann. 6.
2. *C. latifolia*, great. 3. 198. Chalky fields, rare. Ann. 7.
3. *C. Anthriscus*, upright. 14. 987. Hedges and banks. Ann. 7.
4. *C. infesta*, spreading. 19. 1314. Fields and hedges. Ann. 7.
5. *C. nodosa*, knotted. 3. 199. Gravelly banks. Ann. 5, 6.

DAUCUS. Carrot.

1. *D. Carota*, wild. 17. 1174. Borders of fields. Bienn. 6, 7.
2. *D. maritimus*, sea-coast. 36. 2560. Cornwall. Bienn. 7, 8.

"Fruit armed with compressed teeth. Leaflets dilated, succulent, hairy, with rounded segments. Umbels convex

when in seed."—About 18 inches high, woolly rather than hairy, of a more fleshy habit than the foregoing. The umbels want the remarkable dark-red central abortive flower, which is characteristic of *D. Carota*. The compressed teeth which clothe the seeds approach to the nature of *D. mauritanicus* and *muricatus*.

BUNIUM. Earth-nut.

1. *B. Bulbocastanum*, common. 14. 988. Pastures. Per. 5, 6.

The *B. Bulbocastanum* and *flexuosum* of Withering, and of Sm. Fl. Brit. 301, prove, on mature examination, to be, as Linnæus considered them, one and the same species. The root of the former, being near the surface, its stem has no elongated tapering base, and if the herb happens to be luxuriant, the leaves of the general involucre are more numerous than otherwise.

CONIUM. Hemlock.

1. *C. maculatum*, common. 17. 1191. Hedges. Bienn. 6, 7.

SELINUM. Milky-parsley.

1. *S. palustre*, marsh. 4. 229. Wet meadows. Per. 7.

ATHAMANTA. Stone-parsley.

1. *A. Libanotis*, mountain. 2. 138. Chalky pastures, rare. Per. 8.

PEUCEDANUM. Sulphur-wort

1. *P. officinale*, sea. 25. 1767. Salt marshes. Per. 6, 7.
2. *P. Silaus*, meadow. 30. 2142. Moist pastures. Per. 8.

CRITHMUM. Sampire.

1. *C. maritimum*, sea. 12. 819. Sea cliffs. Per. 8.

HERACLEUM. Cow-parsnep.

1. *H. Sphondylium*, common. 14. 939. Borders of fields. Bienn. 7.

H. angustifolium, Fl. Brit. 307, proves, on a careful examination, to be only a narrow-leaved variety of this, distinct from the true *angustifolium* of Linnæus.

LIGUSTICUM. Lovage.

1. *L. scoticum*, Scottish. 17. 1207. Scottish coast. Per. 7.
2. *L. cornubiense*, Cornish. 10. 683. Thickets, Cornwall. Per. 7.
3. *L. Meum*, spignel. 32. 2249. Mountain pastures. Per. 5.

ANGELICA. Angelica.

- *1. *A. Archangelica*, garden. 36. 2561. Wet meadows, rare. Bienn. 9.
2. *A. sylvestris*, wild. 16. 1128. Watery places. Per. 7.

SIUM. Water-parsnep.

1. *S. latifolium*, broad-leaved. 3. 204. Rivers and ditches. Per. 7, 8.
2. *S. angustifolium*, narrow-leaved. 2. 139. Rivers and ditches. Per. 7, 8.
3. *S. nodiflorum*, procumbent. 9. 639. Ditches and rivulets. Per. 7, 8.
4. *S. repens*, creeping. 20. 1431. Watery ground. Per. 6—8.
5. *S. verticillatum*, whorled. 6. 395. Salt meadows. Per. 7, 8.

PLANTS.

SISON. Hone-wort.

1. *S. Amomum*, hedge. 14. 954. Moist chalk or marl. Ann. 8.
2. *S. segetum*, corn. 4. 228. Chalky fields, rare. Ann. 8.

OENANTHE. Water-Dropwort.

1. *O. fistulosa*, common. 6. 363. Ditches and bogs. Per. 7, 8.
2. *O. pimpinelloides*, parsley. 5. 347. Salt marshes. Per. 7.
3. *O. peucedanifolia*, sulphur-wort. 5. 348. Ditches and bogs. Per. 6.
4. *O. crocata*, hemlock. 33. 2313. Watery places. Per. 7.

CORIANDRUM. Coriander.

- *1. *C. sativum*, common. 1. 67. Fields and dunghills, rare. Ann. 6.

PHELLANDRIUM. Water-Hemlock.

1. *P. aquaticum*, common. 10. 684. Ditches and rivers. Bienn. 6, 7.

CICUTA. Cowbane.

1. *C. virofa*, water. 7. 479. Rivers and ditches. Per. 8.

AETHUSA. Fool's-Parsley.

1. *A. Cynapium*, common. 17. 1192. Cultivated ground. Ann. 7, 8.

SCANDIX. Chervil.

1. *S. odorata*, great or sweet. 10. 697. Mountain pastures. Per. 5.
2. *S. Peæden-Veneris*, needle. 20. 1397. Corn-fields. Ann. 6, 7.
- *3. *S. Cerfolium*, garden. 18. 1268. Banks and hedges. Ann. 6.
4. *S. Anthriscus*, rough. 12. 818. Hedges and rubbish. Ann. 5.

CHEEROPHYLLUM. Cow-Parsley.

1. *C. sylvestre*, smooth-stalked. 11. 752. Hedges and thickets. Per. 4, 5.
2. *C. temulentum*, rough-stalked. 22. 1521. Hedges and groves. Bienn. 6, 7.
3. *C. aureum*, tawny-seeded. 30. 2103. Borders of fields, Scotland. Per. 6.

IMPERATORIA. Master-wort.

1. *I. Ostruthium*, great. 20. 1380. Moist mountain pastures. Per. 6.

PASTINACA. Parsnep.

1. *P. fativa*, wild. 8. 556. Chalky banks. Bienn. 7.

SMYRNIUM. Alexanders.

1. *S. Olusatrum*, common. 4. 230. Ruins, and sea cliffs. Bienn. 5.

ANETHUM. Fennel.

1. *A. Feniculum*, common. 17. 1208. Chalk cliffs. Bienn. 7, 8.

CARUM. Caraway.

- *1. *C. Carui*, common. 21. 1503. Meadows and pastures. Bienn. 6.

PIMPINELLA. Burnet-Saxitrage.

1. *P. saxifraga*, common. 6. 407. Dry chalky pastures. Per. 7, 8.
2. *P. magna*, great. 6. 408. Limestone groves. Per. 7, 8.
3. *P. dioica*, dwarf. 17. 1209. Limestone rocks, rare. Per. 5, 6.

APIUM. Celery.

1. *A. graveolens*, wild. 17. 1210. Ditches and marshes. Bienn. 8.

AEGOPIDIUM. Gout-weed.

1. *A. Podagraria*, common. 14. 940. Shady cultivated ground. Per. 5, 6.

Ord. 3. Trigynia.

VIBURNUM. Guelder-rose.

1. *V. Lantana*, mealy. 5. 331. Chalky hedges. Shrub. 5.
2. *V. Opulus*, common. 5. 332. Watery groves and hedges. Shrub. 6.

SAMBUCUS. Elder.

1. *S. Ebulus*, dwarf. 7. 475. Waste ground, rare. Per. 7.
2. *S. nigra*, common. 7. 476. Wood and hedges. Small tree. 6.

STAPHYLEA. Bladder-nut.

- *1. *S. pinnata*, common. 22. 1560. Hedges, rare. Shrub. 6.

TAMARIX. Tamarisk.

1. *T. gallica*, common, or French. 19. 1318. South coast. Shrub. 7.

CORRIGIOLA. Strap-wort.

1. *C. littoralis*, sand. 10. 668. South-west coast. Ann. 7, 8.

Ord. 4. Tetragynia.

PARNASSIA. Grass of Parnassus.

1. *P. palustris*, common. 2. 82. Boggymoores. Per. 9, 10.

Ord. 5. Pentagynia.

STATICE. Sea Lavender.

1. *S. Armeria*, thrift. 4. 226. Mountains, and sea shore. Per. 7, 8.
2. *S. Limonium*, common. 2. 102. Muddy sea shore. Per. 7, 8.
3. *S. reticulata*, matted. 5. 328. Norfolk coast. Per. 7, 8.

LINUM. Flax.

1. *L. usitatissimum*, common. 19. 1357. Fields. Ann. 7.
2. *L. perenne*, perennial blue. 1. 40. Chalky hills. Per. 6, 7.
3. *L. angustifolium*, narrow-leaved pale. 6. 381. Sand or limestone. Per. 7.
4. *L. catharticum*, purging. 6. 380. Dry pastures. Ann. 6-8.

SIBBALDIA. Sibbaldia.

1. *S. procumbens*, procumbent. 13. 897. Scottish mountains. Per. 7.

Ord. 6.

PLANTS.

Ord. 6. *Hexagynia.*

DROSEREA. Sun-dew.

1. *D. rotundifolia*, round-leaved. 13. 867. Turfy bogs. Per. 7, 8.
2. *D. longifolia*, long-leaved. 13. 868. Turfy bogs. Per. 7, 8.
3. *D. anglica*, great. 13. 869. Bogs, rare. Per. 7, 8.

Ord. 7. *Polygynia.*

MYOSURUS. Moufetail.

1. *M. minimus*, least. 7. 435. Gravelly corn-fields. Ann. 5.

Class 6. HEXANDRIA.

Ord. 1. *Monogynia.*

GALANTHUS. Snowdrop.

1. *G. nivalis*, common. 1. 19. Meadows and orchards. Per. 2.

LEUCOJUM. Snowflake.

1. *L. aestivum*, summer. 9. 621. Moist meadows. Per. 5.

NARCISSUS. Narcissus.

1. *N. poeticus*, poetic. 4. 275. Sandy downs. Per. 5.
2. *N. biflorus*, pale. 4. 276. Sandy downs. Per. 4, 5.
3. *N. Pseudo-narcissus*, daffodil. 1. 17. Woods and pastures. Per. 3.

ALLIUM. Garlick.

1. *A. Ampeloprasum*, great round. 24. 1657. Severn isles. Per. 7.
2. *A. arenarium*, sand. 19. 1358. Mountain woods. Per. 7.
3. *A. carinatum*, mountain. 24. 1658. Rocks and mountains. Per. 7.
4. *A. oleraceum*, streaked field. 7. 488. Fields. Per. 7.
5. *A. vineale*, crow. 28. 1974. Chalky hills and fields. Per. 7.
6. *A. ursinum*, broad-leaved. 2. 122. Groves and thickets. Per. 5, 6.
7. *A. Schoenoprasum*, chive. 34. 2441. Meadows and pastures, rare. Per. 6.

FRTLILLARIA. Fritillary.

1. *F. Meleagris*, common. 9. 622. Moist pastures. Per. 4.

TULIPA. Tulip.

1. *T. sylvestris*, wild yellow. 1. 63. Chalk-pits, rare. Per. 4.

ORNITHOGALUM. Star of Bethlehem.

1. *O. luteum*, yellow. 1. 21. Groves, rare. Per. 4.
2. *O. pyrenaicum*, spiked. 7. 499. Pastures and hills, rare. Per. 6, 7.
3. *O. umbellatum*, common. 2. 130. Meadows and pastures. Per. 4, 5.
4. *O. nutans*, drooping. 28. 1997. Dry meadows, rare. Per. 5.

HYACINTHUS. Hyacinth.

1. *H. racemosus*, starch. 27. 1391. Sandy ground, and walks. Per. 5.

SCILLA. Squill.

1. *S. verna*, vernal. 1. 23. Sea cliffs. Per. 4.
2. *S. bifolia*, two-leaved. 1. 24. Woods in the west. Per. 3, 4.
3. *S. autumnalis*, autumnal. 2. 78. Dry pastures, rare. Per. 9.
4. *S. nutans*, hare-bell. 6. 377. Groves and pastures. Per. 5.

ANTHERICUM. Spider-wort.

1. *A. ferotinum*, mountain. 12. 793. Welsh mountains. Per. 6.

NARTHECIUM. Asphodel.

1. *N. officragum*, Lancashire. 8. 535. Turfy bogs. Per. 7, 8.

ASPARAGUS. Sperage.

1. *A. officinalis*, common. 5. 339. Stony sea-coast. Per. 8.

CONVALLARIA. Lilly of the Valley.

1. *C. majalis*, common. 15. 1035. Groves and thickets. Per. 5.
2. *C. verticillata*, narrow-leaved Solomon's seal. 2. 128. Woods, Scotland. Per. 6.
3. *C. Polygonatum*, angular Solomon's seal. 4. 280. Woods, rare. Per. 5, 6.
4. *C. multiflora*, common Solomon's seal. 4. 279. Woods. Per. 5, 6.

ACORUS. Sweet Flag.

1. *A. Calamus*, common. 5. 356. Watery places. Per. 6.

JUNCUS. Rush.

1. *J. acutus*, great sharp. 23. 1614. Sandy sea-coast. Per. 7.
2. *J. maritimus*, lesser sharp. 24. 1725. Muddy sea-coast. Per. 8.
3. *J. glaucus*, hard. 10. 665. Moist pastures. Per. 7.
4. *J. conglomeratus*, common. 12. 835. Moist pastures. Per. 7.
5. *J. effusus*, soft. 12. 836. Moist pastures. Per. 7.
6. *J. filiformis*, least. 17. 1175. Alpine rills. Per. 8.
7. *J. trifidus*, three-leaved. 21. 1482. Alpine bogs. Per. 7.
8. *J. squarrosus*, moss. 13. 933. Sandy heaths. Per. 6, 7.
9. *J. acutiflorus*, sharp-flowered jointed. 4. 238, (*articulatus*). Bogs. Per. 6.

"Leaves with knotty joints, slightly compressed. Stem without joints. Panicle repeatedly forked, dense. Calyx-leaves all sharp-pointed."—*Stem* leafy. *Panicle* spreading, with upright branches. *Flowers* small.

10. *J. lampocarpus*, shining-fruited jointed. 30. 2143. Boggy ground. Per. 6, 7.

"Leaves with knotty joints, compressed. Stem without joints. Panicle compound, erect, elongated. Inner calyx-leaves bluntish, bordered. Capsule coloured, varnished."—*Stem* leafy. *Panicle* tall, many-flowered. *Capsule* large, of a dark chocolate hue, and highly polished.

11. *J. obtusiflorus*, blunt-flowered jointed. 30. 2144. Marshes. Per. 7, 8.

"Leaves and stem with knotty joints, cylindrical. Panicle repeatedly compound; its branches divaricated and reflexed. Calyx-leaves obtuse, as long as the capsule."—

Stem

PLANTS.

Stem tall, but with only two leaves. Flowers and capsule small, brownish.

12. *J. uliginosus*, little bulbous. 12. 801. Wet sandy heaths. Per. 6, 7.
 13. *J. bulbosus*, round-fruited. 13. 934. Moist pastures. Per. 7.
 14. *J. gracilis*, slender spreading. 31. 2174. Alpine bogs, rare. Per. 7.
- “Leaves linear, flat. Stem forked, racemose, taller than the leaves. Flowers solitary.”
15. *J. bufonius*, toad. 12. 802. Sandy wet places. Ann. 7, 8.
 16. *J. biglumis*, two-flowered. 13. 898. Alpine rills, rare. Per. 8.
 17. *J. triglumis*, three-flowered. 13. 899. Alpine rills. Per. 7.
 18. *J. castaneus*, clustered alpine. 13. 900. Highland bogs. Per. 7.
 19. *J. pilosus*, broad-leaved hairy. 11. 736. Woods and groves. Per. 3, 4.
 20. *J. Forsteri*, narrow-leaved hairy. 18. 1293. Groves. Per. 5.
 21. *J. sylvaticus*, wood. 11. 737. Woods and thickets. Per. 5.
 22. *J. campestris*, hairy field. 10. 672. Barren pastures. Per. 4, 5.
 23. *J. spicatus*, spiked. 17. 1176. Highland hills. Per. 7.

BERBERIS. Barberry.

1. *B. vulgaris*, common. 1. 49. Chalky banks. Shrub. 5, 6.

FRANKENIA. Sea-Heath.

1. *F. lewis*, smooth. 3. 205. Muddy salt-marshes. Per. 7.
2. *F. pulverulenta*, powdery. 31. 2222. Suffex coast. Ann. 7.

PEPLIS. Water-Purslane.

1. *P. portula*, common. 17. 1211. Watery places. Ann. 7, 8.

Ord. 2. Trigynia.

RUMEX. Dock.

1. *R. sanguineus*, bloody-veined. 22. 1533. Woods and way sides. Per. 7.
2. *R. crispus*, curled. 28. 1998. Rubbish and pastures. Per. 6, 7.
3. *R. acutus*, sharp. 11. 724. Watery and waste places. Per. 7.
4. *R. obtusifolius*, broad-leaved. 28. 1999. Waste ground. Per. 7, 8.
5. *R. pulcher*, fiddle. 22. 1576. Gravelly pastures. Per. 8.
6. *R. maritimus*, golden. 11. 725. Salt marshes. Per. 7, 8.
7. *R. palustris*, yellow marsh. 27. 1932. Marshes and ditches. Per. 7, 8.
8. *R. aquaticus*, great water. 30. 2104. Ditches and rivers. Per. 7, 8.
9. *R. digynus*, mountain forrel. 13. 910. Alpine rivulets. Per. 6.
10. *R. acetosa*, common forrel. 2. 127. Meadows and pastures. Per. 6.
11. *R. acetosella*, sheep's forrel. 24. 1674. Gravelly fields. Per. 6, 7.

TOFIELDIA. Tofieldia.

1. *T. palustris*, Scottish asphodel. 8. 536. Alpine rills. Per. 8.

SCHEUCHZERIA. Scheuchzeria.

1. *S. palustris*, marsh. 26. 1801. Bogs, Yorkshire. Per. 6.

TRIGLOCHIN. Arrow-grafs.

1. *T. palustre*, marsh. 6. 366. Marshes. Per. 7.
2. *T. maritimum*, sea. 4. 255. Muddy salt-marshes. Per. 5—8.

COLCHICUM. Meadow-Saffron.

1. *C. autumnale*, common. 2. 133. β . 20. 1432. Rich meadows. Per. 9.

Ord. 3. Polygynia.

ALISMA. Water-Plantain.

1. *A. Plantago*, greater. 12. 837. Ditches and pools. Per. 7.
2. *A. Damasonium*, star-headed. 23. 1615. Gravelly pools, rare. Per. 6, 7.
3. *A. natans*, floating. 11. 775. Alpine lakes, rare. Per. 7, 8.
4. *A. ranunculoides*, small. 5. 326. Watery turfy bogs. P. 8.

Class 7. HEPTANDRIA.

Ord. 1. Monogynia.

TRIENTALIS. Trientalis.

1. *T. europæa*, chickweed. 1. 15. Woods and mountain heaths. Per. 5, 6.

Class 8. OCTANDRIA.

Ord. 1. Monogynia.

OENOTHERA. Evening-Primrose.

1. *O. biennis*, common. 22. 1534. Sandy western coast. Bienn. 7—9.

EPILOBIUM. Willow-herb.

1. *E. angustifolium*, rose-bay. 28. 1947. Shady meadows. Per. 7.
2. *E. hirsutum*, great hairy. 12. 838. Watery places. Per. 7.
3. *E. parviflorum*, small-flowered, hoary. 12. 795. Watery places. Per. 7.
4. *E. montanum*, broad smooth-leaved. 17. 1177. Groves and stony places. Per. 7.
5. *E. roseum*, pale smooth-leaved. 10. 693. Boggy ground, rare. Per. 7.
6. *E. tetragonum*, square-stalked. 28. 1948. Marshes. Per. 7.
7. *E. palustre*, round-stalked, marsh. 5. 346. Marshes. Per. 7.
8. *E. alpinifolium*, chickweed-leaved. 28. 2000. Mountain rills. Per. 7.

“Leaves on footstalks, ovate, acute, toothed. Stigma undivided. Root creeping, matted. Stems decumbent, obtusely quadrangular.”—Mr. Winch has shewn this to be the

PLANTS.

the plant of the Cheviot hills, described by Ray, which has always been taken for *alpinum*.

9. *E. alpinum*, alpine. 28. 2001. Alpine rivulets, Scotland. Per. 6, 7.

CHLORA. Yellow-Centaury.

1. *C. perfoliata*, common. 1. 60. Chalky banks. Ann. 7, 8.

VACCINIUM. Whortle-berry.

1. *V. Myrtillus*, bilberry. 7. 456. Heaths and woods. Shrub. 5.
 2. *V. uliginosum*, great bilberry. 9. 581. Marshy heaths. Shrub. 4, 5.
 3. *V. Vitis Idæa*, red. 9. 598. Dry stony moors. Shrubby. 6.
 4. *V. Oxycoccus*, cranberry. 5. 319. Mossy bogs. Per. 6.

MENZIESIA. Menziesia.

1. *M. cærulea*, Scottish. 35. 2469. West of Scotland. Shrubby. 6, 7.
 2. *M. Dabeoci*, Irish. 1. 35. (*Erica Dabeoci*.) West of Ireland. Shrubby. 6, 7.

ERICA. Heath.

1. *E. vulgaris*, common. 15. 1013. Heaths and woods. Shrub. 6, 7.
 2. *E. Tetralix*, cross-leaved. 15. 1014. Bogs. Shrubby. 7, 8.
 3. *E. cinerea*, fine-leaved. 15. 1015. Heaths. Shrub. 7, 8.
 4. *E. vagans*, Cornish. 1. 3. Heaths, Cornwall. Shrub. 7, 8.

DAPHNE. Mezereon.

1. *D. Mezereum*, spurge-olive. 20. 1381. Woods, rare. Shrub. 3, 4.
 2. *D. Laureola*, spurge-laurel. 2. 119. Bushy places. Shrub. 3.

ACER. Maple.

- *1. *A. Pseudo-platanus*, greater, or sycamore. 5. 303. Woods. Tree. 5.
 2. *A. campestre*, common. 5. 304. Woods and hedges. Tree. 5, 6.

Ord. 2. Trigynia.

POLYGONUM. Persicaria.

1. *P. amphibium*, amphibious. 7. 436. Ponds and ditches. Per. 7, 8.
 2. *P. Persicaria*, spotted. 11. 756. Ditches and bogs. Ann. 7, 8.
 3. *P. lapathifolium*, pale-flowered. 20. 1382. Dughills. Ann. 7, 8.
 4. *P. Hydro Piper*, biting. 14. 989. Watery places. Ann. 9.
 5. *P. minus*, small creeping. 15. 1043. Gravelly puddles. Ann. 9.
 6. *P. Biflora*, great bistort. 8. 509. Meadows. Per. 6.
 7. *P. viviparum*, alpine bistort. 10. 669. Highland mountains. Per. 6, 7.
 8. *P. aviculare*, knot-grass. 18. 1252. Rubbish and sand. Ann. 4—10.
 *9. *P. Fagopyrum*, buck-wheat. 15. 1044. Fields. Ann. 7, 8.

Vol. XXVII.

10. *P. Convolvulus*, black bindweed. 14. 941. Cornfields. Ann. 6, 7.

Ord. 3. Tetragynia.

PARIS. Herb Paris.

1. *P. quadrifolia*, common. 1. 7. Shady groves. Per. 5.

ADOXA. Moschatell.

1. *A. Moschatellina*, tuberous. 7. 453. Groves and banks. Per. 4, 5.

ELATINE. Waterwort.

1. *E. Hydro Piper*, small. 14. 955. Borders of lakes, rare. Ann. 8.

Class 9. ENNEANDRIA.

Ord. 1. Hexagynia.

BUTOMUS. Flowering-Rush.

1. *B. umbellatus*, common. 10. 651. Rivers and ditches. Per. 6, 7.

Class 10. DECANDRIA.

Ord. 1. Monogynia.

MONOTROPA. Bird's-nest.

1. *M. Hypopithys*, yellow. 1. 69. Beech or Fir woods. Per. 6.

ANDROMEDA. Andromeda.

1. *A. polifolia*, marsh. 10. 713. Turfy bogs. Shrubby. 6.

ARBUTUS. Arbutus.

1. *A. Unedo*, strawberry tree. 34. 2377. Rocks, Ireland. Shrub. 9.
 2. *A. alpina*, black-berried alpine. 29. 2030. Stony hills, rare. Shrubby. 5.
 3. *A. Uva ursi*, red-berried trailing. 10. 714. Alpine moors. Shrubby. 6.

PYROLA. Winter-green.

1. *P. rotundifolia*, round-leaved. 3. 213. Mountain thickets, rare. Per. 7.
 2. *P. media*, intermediate. 28. 1945. North of England, woods. Per. 6.
 3. *P. rosea*, rose-coloured. 36. 2543. North of England, woods. Per. 7.
 4. *P. minor*, lesser. 3. 158? Woods, and mountain thickets. Per. 7.
 5. *P. secunda*, ferrated. 8. 517. Alpine woods. Per. 7.
 6. *P. uniflora*, single-flowered. 3. 146. Alpine woods, rare. Per. 7.

Ord. 2. Digynia.

CHRYSOSPLENIUM. Golden-Saxifrage.

1. *C. alternifolium*, alternate-leaved. 1. 54. Shady rills, rare. Per. 5.
 2. *C. oppositifolium*, opposite-leaved. 7. 490. Shady rills. Per. 5.

4 M

SAXIFRAGA.

PLANTS.

SAXIFRAGA. Saxifrage.

1. *S. stellaris*, hairy. 3. 167. Mountain rivulets. Per. 6, 7.
2. *S. nivalis*, clustered alpine. 7. 440. Tops of Highland mountains. Per. 7.
3. *S. umbrosa*, London pride. 10. 663. Mountains. Per. 6.
4. *S. hirsuta*, hairy oval-leaved. 33. 2322. Mountains, Ireland. Per. 6.
5. *S. Geum*, kidney-leaved. 22. 1561. Mountains, Ireland. Per. 6.
6. *S. oppositifolia*, purple. 1. 9. Alpine rocks. Per. 4.
7. *S. Hirculus*, yellow marsh. 15. 1009. Turfy bogs, very rare. Per. 8.
8. *S. aizoides*, yellow mountain. 1. 39. Mountain rivulets. Per. 7, 8.
9. *S. granulata*, white. 7. 500. Meadows and pastures. Per. 5.
10. *S. cernua*, drooping bulbous. 10. 664. Wet alpine rocks. Per. 7.
11. *S. rivularis*, alpine brook. 32. 2275. Alpine rivulets. Per. 6, 7.
12. *S. tridactylites*, rue-leaved. 7. 501. Walls. Ann. 5.
13. *S. caespitosa*, tufted alpine. 12. 794. Alpine rocks, rare. Per. 6.
14. *S. moschata*, musky alpine. 33. 2314. Alpine rocks, rare. Per. 6, 7.
15. *S. palmata*, palmate. 7. 455. Rocky mountains. Per. 5, 6.
16. *S. hirta*, trifid hairy. 32. 2291. Highlands of Scotland. Per. 5, 6.
17. *S. platyptala*, broad-petalled. 32. 2276. Snowdon, and Scotland. Per. 6.
18. *S. elongella*, long-stalked. 32. 2277. Scottish mountains. Per. 6.
19. *S. hypnoides*, mossy cushion. 7. 454. Mountains. Per. 5, 6.
20. *S. pedatifida*, pedatifid. 32. 2278. Highlands of Scotland. Per. 5, 6.

SCLERANTHUS. Knawel.

1. *S. annuus*, annual. 5. 351. Sandy fields, common. Ann. 7.
2. *S. perennis*, perennial. 5. 352. Sandy heaths, rare. Per. 10, 11.

SAPONARIA. Soapwort.

1. *S. officinalis*, common. 15. 1060. Meadows and hedges. Per. 8, 9.

DIANTHUS. Pink.

1. *D. Armeria*, Deptford. 5. 317. Gravelly pastures. Ann. 7, 8.
2. *D. prolifer*, proliferous. 14. 956. Gravelly banks, rare. Ann. 7.
3. *D. Caryophyllus*, clove. 3. 214. Walls. Per. 7.
4. *D. deltoides*, maiden. 1. 61. Gravelly pastures. Per. 7—10.
5. *D. caesus*, mountain. 1. 62. Dry limestone rocks, rare. Per. 6, 7.

Ord. 3. Trigynia.

CUCUBALUS. Berry-Chickweed.

1. *C. baccifer*, black-fruited. 22. 1577. Anglesea, *Dillenius*. Per. 6, 7.

SILENE. Catchfly.

1. *S. anglica*, English. 17. 1178. Sandy fields. Ann. 7.
 2. *S. quinquevulnera*, variegated. 2. 86. Sandy fields. Ann. 6, 7.
 3. *S. nutans*, Nottingham. 7. 465. Calcareous rocks. Per. 6, 7.
- S. paradoxa*, mentioned in the Fl. Brit. 467, is to be excluded, as not really of British growth. The Dover Catchfly, *Lychnis major noctiflora Dubrensis perennis*, Raii Syn. 340, has not been found since the time of Ray; and the old specimens, preserved in the British Museum, appear to be something unknown to modern botanists, though not sufficiently perfect to afford specific characters. They are most like the Linnæan *Cucubalus viscosus*, for which Ray's plant was originally taken by Linnæus and Hudson.
4. *S. inflata*, bladder. 3. 164. Fields and banks, common. Per. 7.
 5. *S. maritima*, sea. 14. 957. Stony shores and mountains. Per. 8, 9.
 6. *S. Otites*, Spanish. 2. 85. Dry fields and heaths, rare. Per. 7, 8.
 7. *S. conica*, corn. 13. 922. Sandy corn-fields. Ann. 7.
 8. *S. noctiflora*, night-flowering. 5. 291. Gravelly fields. Ann. 7.
 - *9. *S. Armeria*, common, or Lobel's. 20. 1398. Fields and banks. Ann. 7, 8.
 10. *S. acaulis*, moss. 16. 1081. Mountains. Per. 6, 7.

STELLARIA. Stitchwort.

1. *S. nemorum*, wood. 2. 92. Moist woods, in the north. Per. 5, 6.
2. *S. media*, common chickweed. 8. 537. Waste and cultivated ground. Ann. 4—10.
3. *S. hololea*, greater. 8. 511. Dry groves. Per. 5.
4. *S. graminea*, lesser. 12. 803. Pastures and bushes. Per. 5.
5. *S. glauca*, glaucous marsh. 12. 825. Wet meadows. Per. 6, 7.
6. *S. uliginosa*, bog. 15. 1075. Watery places. Ann. 6.
7. *S. scapigera*, many-stalked. 18. 1269. Rivulets, Scotland. Per. 6.
8. *S. cerasoides*, alpine. 13. 911. Highland mountains. Per. 6.

ARENARIA. Sandwort.

1. *A. peploides*, sea. 3. 189. Sandy beach. Per. 6, 7.
2. *A. trinervis*, plantain-leaved. 21. 1483. Groves. Ann. 5, 6.
3. *A. serpyllifolia*, thyme-leaved. 13. 923. Banks and walls. Ann. 6, 7.
4. *A. rubra*, purple. 12. 852. Sandy fields. Ann. 7, 8.
5. *A. marina*, sea spurrey. 14. 958. Sandy beach. Ann. 6, 7.
6. *A. tenuifolia*, fine-leaved. 4. 219. Sand and walls. Ann. 6.
7. *A. verna*, vernal. 8. 512. Sparry hills. Per. 5—8.
8. *A. fastigiata*, level-topped. 25. 1744. Scottish mountains. Ann. 6.
9. *A. ciliata*, fringed. 25. 1745. Irish mountains. Per. 8.

CHELERIA. Cherleria.

1. *C. sedoides*, dwarf. 17. 1212. Highland mountains. Per. 7.

Ord.

PLANTS.

Ord. 4. *Pentagynia*.

COTYLEDON. Navelwort.

1. *C. Umbilicus*, common. 5. 325. Shady rocks. Per. 6, 7.
2. *C. lutea*, greater yellow. 22. 1522. Moist rocks and walls, rare. Per. 6.

SEDUM. Stone-crop.

1. *S. Telephium*, orpine. 19. 1319. Fields and thickets. Per. 8.
2. *S. dasycyllum*, thick-leaved. 10. 656. Walls and stones. Per. 6.
3. *S. anglicum*, English. 3. 171. Mountains, and sea shore. Ann. 7.
4. *S. acre*, biting. 12. 839. Walls and dry sand. Per. 6.
5. *S. sexangulare*, insipid. 28. 1946. Walls, rare. Per. 6, 7.
6. *S. villosum*, hairy. 6. 394. Mountain rills. Per. 6, 7.
7. *S. album*, white. 22. 1578. Rocks and walls, rare. Per. 7.
8. *S. reflexum*, yellow. 10. 695. Walls and roofs, common. Per. 7.
9. *S. glaucum*, glaucous. 35. 2477. Barren sands. Per. 7, 8.
10. *S. rupestre*, rock. 3. 170. Rocks, rare. Per. 7.
11. *S. Forsterianum*, Forsterian. 26. 1802. Rocks, Wales. Per. 7.

OXALIS. Wood-Sorrel.

1. *O. Acetofella*, common. 11. 762. Woods. Per. 4, 5.
2. *O. corniculata*, yellow procumbent. 24. 1726. Shady rocks. Per. 5—10.

AGROSTEMMA. Cockle.

1. *A. Githago*, corn. 11. 741. Corn-fields. Ann. 6, 7.

LYCHNIS. Campion.

1. *L. Flos cuculi*, ragged robin. 8. 573. Moist meadows. Per. 6.
2. *L. Viscaria*, German catchfly. 11. 788. Rocks; rare. Per. 5, 6.
3. *L. alpina*, red alpine. 32. 2254. Highland rocks. Per. 6, 7.
4. *L. dioica*, red or white. 22. 1579, 1580. Groves, and fields. Per. 5—9.

CERASTIUM. Chickweed.

1. *C. vulgatum*, broad mouse-ear. 11. 789. Pastures and rubbish. Ann. 4, 5.
2. *C. viscosum*, narrow mouse-ear. 11. 790. Pastures and rubbish. Per. 5—9.
3. *C. femidecandrum*, little mouse-ear. 23. 1630. Walls and sand. Ann. 4, 5.
4. *C. tetrandrum*, tetrandrous mouse-ear. 3. 166. Rocks and sand, Scotland. Ann. 5, 6.
5. *C. arvense*, field. 2. 93. Gravelly fields. Per. 5—8.
6. *C. alpinum*, alpine. 7. 472. Alpine rills. Per. 6, 7.
7. *C. latifolium*, broad rough. 7. 473. Alpine rocks. Per. 6.
8. *C. aquaticum*, water. 8. 538. Watery places. Per. 7.

SPERGULA. Spurrey.

1. *S. arvensis*, rough-seeded corn. 22. 1535. Sandy fields. Ann. 7, 8.

2. *S. pentandra*, smooth-seeded corn. 22. 1536. Sandy fields. Ann. 7, 8.
3. *S. nodosa*, knotted. 10. 694. Moist sandy heaths. Per. 7, 8.
4. *S. faginoides*, smooth awl-shaped. 30. 2105. Highland mountains. Per. 6.
5. *S. subulata*, ciliated awl-shaped. 16. 1082. Sandy heaths. Per. 7, 8.

Class II. DODECANDRIA.

Ord. 1. *Monogynia*.

ASARUM. Afarabacca.

1. *A. europæum*, common. 16. 1083. Woods, rare. Per. 5.

LYTHRUM. Lythrum.

1. *L. Salicaria*, purple. 15. 1061. Watery places. Per. 7, 8.
2. *L. hyssopifolia*, hyssop-leaved. 5. 292. Inundated ground. Ann. 8.

Ord. 2. *Digynia*.

AGRIMONIA. Agrimony.

1. *A. Eupatoria*, common. 19. 1335. Thickets and hedges. Per. 6, 7.

Ord. 3. *Trigynia*.

RESEDA. Mignonette.

1. *R. Luteola*, dyer's-weed. 5. 320. Fields and rubbish. Ann. 7.
2. *R. lutea*, wild, or bafe rocket. 5. 321. Fields and chalky hills. Ann? 7, 8.

EUPHORBIA. Spurge.

1. *E. Peplis*, purple. 28. 2002. Sandy fourth coast. Ann. 7, 8.
2. *E. Peplus*, petty. 14. 959. Cultivated ground, common. Ann. 7, 8.
3. *E. exigua*, dwarf. 19. 1336. Corn-fields, rare. Ann. 7.
4. *E. Lathyris*, caper. 32. 2255. Dry stony places, rare. Bienn. 5, 6.
5. *E. Portlandica*, Portland. 7. 441. South coast. Per. 8.
6. *E. paralia*, sea. 3. 195. Sandy sea shore. Per. 8, 9.
7. *E. helioscopia*, sun. 13. 883. Cultivated ground. Ann. 7, 8.
8. *E. platyphylla*, warty. 5. 333. Corn-fields, rare. Ann. 7, 8.
9. *E. Esula*, leafy-branched. 20. 1399. Woods, Scotland. Per. 7.
10. *E. Cyparissias*, cyprefs. 12. 840. Woods and barren ground. Per. 5, 6.
11. *E. hiberna*, Irish. 19. 1337. Fields, rare. Per. 6.
12. *E. amygdaloides*, wood. 4. 256. Woods and groves. Per. 3, 4.
13. *E. Characias*, red. 7. 442. Mountainous places, rare. Shrub. 3, 4.

Ord. 4. *Dodecagynia*.

SEMPERVIVUM. Houfeleek.

1. *S. tetlorum*, common. 19. 1320. Roofs and walls. Per. 7.

PLANTS,

Class 12. ICOSANDRIA.

Ord. 1. *Monogynia*.

PRUNUS. Cherry or Plum.

1. *P. Padus*, bird cherry. 20. 1383. Woods and hedges. Tree. 5.
2. *P. Cerasus*, common cherry. 10. 706. Woods and hedges. Tree. 5.
- *3. *P. domestica*, common plum. 25. 1783. Hedges. Tree. 4.
4. *P. infinitia*, bullace. 12. 841. Hedges and groves. Tree. 4.
5. *P. spinosa*, sloe. 12. 842. Hedges and thickets. Shrub. 3, 4.

Ord. 2. *Pentagynia*.

MESPILUS. Medlar.

1. *M. Oxyacantha*, hawthorn. 35. 2504. Hedges and thickets. Small tree. 5, 6.
- *2. *M. germanica*, common eatable. 22. 1523. Hedges, rare. Tree. 5.

PYRUS. Pear.

1. *P. communis*, common. 25. 1784. Woods and hedges. Tree. 4.
2. *P. Malus*, apple, or crab. 3. 179. Woods and hedges. Tree. 5.
3. *P. torminalis*, wild service. 5. 298. Woods and hedges. Tree. 4, 5.
4. *P. domestica*, true service. 5. 350. Mountain woods, rare. Tree. 5.
5. *P. aucuparia*, mountain ash. 5. 337. Mountain woods. Tree. 5.
6. *P. pinnatifida*, bastard mountain ash. 33. 2331. Rocks, rare. Tree. 5.
7. *P. Aria*, white beam-tree. 26. 1858. Limestone rocks. Tree. 5.

SPIRÆA. Spiræa.

1. *S. salicifolia*, willow-leaved. 21. 1468. Wet mountain thickets. Shrub. 7.
2. *S. Filipendula*, dropwort. 4. 284. Dry open pastures. Per. 7.
3. *S. Ulmaria*, meadow-sweet. 14. 960. Moist meadows. Per. 6, 7.

Ord. 2. *Polygynia*.

ROSA. Rose.

1. *R. spinosissima*, burnet. 3. 187. Sandy heaths. Low shrub. 7.
2. *R. rubella*, red-fruited dwarf. 36. 2521. Northumberland. Low shrub. 7.
3. *R. involuta*, prickly unexpanded. 29. 2068. Western hills. Low shrub. 6.
4. *R. hibernica*, Irish. 31. 2196. Ireland. Shrub. 6—11.
5. *R. arvensis*, white field. 3. 188. Hedges and thickets. Shrub. 6, 7.
6. *R. villosa*, apple. 9. 583. Mountain thickets. Shrub. 6.
7. *R. mollis*, soft-leaved round-fruited. 35. 2459. Thickets. Low shrub. 6.
8. *R. cinnamomea*, cinnamon. 34. 2388. Thickets, Yorkshire. Shrub. 5.
9. *R. tomentosa*, dowys-leaved briar. 14. 990. Woods and hedges. Shrub. 6, 7.

10. *R. rubiginosa*, sweet briar. 14. 991. Gravelly heaths. Shrub. 6, 7.
11. *R. micrantha*, small-flowered sweet briar. 35. 2490. Hedges. Shrub. 6, 7.
12. *R. scabriuscula*, roughish-leaved briar. 27. 1896. Hedges. Shrub. 6.
13. *R. casta*, glaucous-leaved. 33. 2367. Highland valleys. Shrub. 7.
14. *R. canina*, common dog-briar. 14. 992. Hedges. Shrub. 6.
15. *R. collina*, rough-stalked dog-briar. 27. 1895. Thickets, Suffex. 7.
16. *R. dumetorum*, downy-stalked dog-briar. 36. 2579. Thickets, Suffex. 7.

RUBUS. Bramble.

1. *R. idæus*, raspberrry. 34. 2442. Woods and thickets. Shrub. 5, 6.
2. *R. subereæus*, red-fruited. 36. 2572. Northern woods. Shrub. 6.
3. *R. castus*, dew-berry. 12. 826. Groves and hedges. Shrub. 6, 7.
4. *R. corylifolius*, hazel-leaved. 12. 827. Hedges. Shrub. 7.
5. *R. fruticosus*, common. 10. 715. Hedges. Shrub. 7, 8.
6. *R. saxatilis*, stone. 32. 2233. Mountain woods. Per. 6.
7. *R. arcticus*, dwarf crimson. 23. 1585. Stony hills, rare. Per. 5, 6.
8. *R. Chamæmorus*, cloud-berry. 10. 716. Mountain moors. Per. 6.

FRAGARIA. Strawberry.

1. *F. vesca*, common. 22. 1524. Groves and banks. Per. 5, 6.
2. *F. elatior*, hautboy. 31. 2197. Woods in the south, rare. Per. 6, 9.
3. *F. sterilis*, barren. 25. 1785. Barren pastures. Per. 3, 4.

POTENTILLA. Cinquefoil.

1. *P. fruticosa*, shrubby. 2. 88. Mountain thickets, Yorkshire. Shrub. 6.
2. *P. anserina*, silver-weed. 12. 861. Boggy meadows. Per. 6, 7.
3. *P. rupestris*, strawberry-flowered. 29. 2058. Rocks, Wales. Per. 6, 7.
4. *P. argentea*, hoary. 2. 89. Gravelly pastures. Per. 6.
5. *P. aurea*, golden. 8. 561. Highland mountains. Per. 7.
6. *P. verna*, spring. 1. 37. High open pastures. Per. 4, 5.
7. *P. opaca*, faw-leaved hairy. 35. 2449. Highlands. Per. 6.
8. *P. alba*, white. 20. 1384. Welch mountains. Per. 7, 8.
9. *P. reptans*, common creeping. 12. 862. Meadows and pastures. Per. 6—8.
10. *P. tridentata*, trifid-leaved. 34. 2389. Highlands. Per. 5, 6.

TORMENTILLA. Tormentil.

1. *T. officinalis*, common. 12. 863. Heaths and pastures. Per. 6, 7.
2. *T. reptans*, trailing. 12. 864. Hedges, rare. Per. 6, 7.

GEUM.

PLANTS.

GEUM. Avens.

1. *G. urbanum*, common. 20. 1400. Woods and hedges. Per. 5—8.
2. *G. rivale*, water. 2. 106. Moist shady meadows. Per. 6, 7.

DRYAS. Mountain-avens.

1. *D. octopetala*, white. 7. 451. Alpine moors. Per. 7, 8.

COMARUM. Marsh-cinquefoil.

1. *C. palustre*, common. 3. 172. Spongy bogs. Per. 6, 7.

Class 13. POLYANDRIA.

Ord. 1. Monogynia.

ACTÆA. Bane-berries.

1. *A. spicata*, herb christopher. 13. 918. Mountain groves, rare. Per. 5, 6.

CHELIDONIUM. Celandine.

1. *C. majus*, common. 22. 1581. Shady banks. Per. 5, 6.

GLAUCIUM. Horned-poppy.

1. *G. luteum*, yellow. 1. 8. Sandy sea-coast. Per. 7, 8.
- † 2. *G. phoeniceum*, scarlet. 20. 1433. Sandy fields. Ann. 6, 7.
3. *G. violaceum*, violet. 3. 201. Chalky fields, rare. Ann. 5, 6.

PAPAVER. Poppy.

1. *P. hybridum*, mongrel. 1. 43. Chalky fields, rare. Ann. 7.
2. *P. Argemone*, long-rough-headed. 9. 643. Corn-fields. Ann. 6, 7.
3. *P. dubium*, long-smooth-headed. 9. 644. Sandy fields. Ann. 6—8.
4. *P. Rhoeas*, common red. 9. 645. Corn-fields. Ann. 6, 7.
5. *P. foiniferum*, white. 30. 2145. Sandy fen-banks. Ann. 7.
6. *P. cambricum*, yellow. 1. 66. Shady rocks. Per. 6.

NYMPHÆA. Water-lily.

1. *N. alba*, white. 3. 160. Pools, rivers and lakes. Per. 7.

NUPHAR. Yellow water-lily.

1. *N. lutea*, common. 3. 159. Pools and rivers. Per. 7.
2. *N. minima*, least, 32. 2292. Alpine lakes. Per. 7.

TILIA. Lime-tree.

1. *T. europæa*, common. 9. 610. Woods and hedges. Tree. 7.
2. *T. parvifolia*, small-leaved. 24. 1705. Woods. Tree. 8.

CISTUS. Cistus.

1. *C. marifolius*, hoary dwarf. 6. 396. Rocks, rare. Dwarf shrub. 5, 6.
2. *C. guttatus*, spotted-flowered. 8. 544. Sandy pastures, rare. Ann. 6: 7.
3. *C. ledifolius*, ledum-leaved. 34. 2414. Sandy pastures, rare. Ann. 6, 7.
4. *C. furcatus*, dotted-leaved. 31. 2207. Chalk hills, rare. Shrub. 7, 8.
5. *C. Helianthemum*, common dwarf. 19. 1321. Gravelly banks. Shrub. 7, 8.

6. *C. tomentosus*, downy. 31. 2208. Highland hills. Shrubby 7.
7. *C. polifolius*, white mountain. 19. 1322. Open downs. rare. Shrubby 6, 7.

Ord. 2. Pentagynia.

PÆONIA. Pæony.

1. *P. corallina*, entire-leaved. 22. 1513. Severn ifles. Per. 5, 6.

DELPHINIUM. Larkspur.

1. *D. Consolida*, field. 26. 1839. Sandy fields. Ann. 6, 7.

AQUILEGIA. Columbine.

1. *A. vulgaris*, common. 5. 297. Meadows and pastures. Per. 7.

STRATIOTES. Water-aloë.

1. *S. aloides*, common. 6. 379. Ditches and pools. Per. 7.

Ord. 3. Polygynia.

ANEMONE. Anemone.

1. *A. Pulsatilla*, pasque-flower. 1. 51. Chalky hills. Per. 4, 5.
2. *A. nemorosa*, common wood. 5. 355. Groves and heaths. Per. 4, 5.
3. *A. apennina*, blue mountain. 15. 1062. Groves, rare. Per. 4.
4. *A. ranunculoides*, yellow wood. 21. 1484. Groves, rare. Per. 4.

CLEMATIS. Traveller's joy.

1. *C. Vitalba*, common. 9. 612. Hedges, chalky foil. Shrub. 7.

THALICTRUM. Meadow-rue.

1. *T. alpinum*, alpine. 4. 262. Alpine bogs. Per. 6.
2. *T. minus*, lesser. 1. 11. Calcareous pastures. Per. 6, 7.
3. *T. majus*, greater. 9. 611. Mountain thickets. Per. 6, 7.
4. *T. flavum*, common. 6. 367. Moist meadows. Per. 7.

ADONIS. Pheasant's-eye.

1. *A. autumnalis*, corn. 5. 308. Corn-fields. Ann. 5—10.

RANUNCULUS. Crowfoot.

1. *R. Flammula*, lesser spear-wort. 6. 387. Watery places. Per. 6—9.
2. *R. Lingua*, great spear-wort. 2. 100. Ditches. Per. 7.
3. *R. gramineus*, grassy. 33. 2306. Alpine meadows. Per. 5, 6.
4. *R. Ficaria*, pile-wort. 9. 584. Groves and banks. Per. 4.
5. *R. auricomus*, wood. 9. 624. Dry groves. Per. 4, 5.
6. *R. sceleratus*, water. 10. 681. Watery places. Ann. 6—8.
7. *R. alpestris*, alpine white. 34. 2390. Alpine rills. Per. 5.
8. *R. bulbosus*, bulbous. 8. 515. Meadows and pastures. Per. 5.
9. *R. hirsutus*, pale hairy. 21. 1504. Waste and cultivated ground. Ann. 6—10.

R. parvulus of Linnæus, and Fl. Brit. 593, found below Bristol hot-wells by Mr. Dyer, and by several botanists at Montpellier, proves a starved variety of our *hirsutus*, a species

PLANTS.

species unnoticed by Linnæus. Mr. Curtis, in describing the latter, had not adverted to the tuberculated seeds, by which it, in all its varieties, is readily and essentially distinguished from *bulbosus*.

10. *R. repens*, creeping. 8. 516. Meadows and rubbish. Per. 6-8.
11. *R. acris*, upright meadow. 10. 652. Meadows and pastures. Per. 6, 7.
12. *R. arvensis*, corn. 2. 135. Corn-fields. Ann. 6.
13. *R. parviflorus*, small-flowered. 2. 120. Gravelly fields. Ann. 5, 6.
14. *R. hederaceus*, ivy-leaved. 28. 2003. Inundated places. Per. 5-8.
15. *R. aquatilis*, white floating. 2. 101. Ditches, pools, and rivers. Per. 5, 6.

TROLLIUS. Globe-flower.

1. *T. europæus*, common. 1. 28. Mountain groves. Per. 5, 6.

HELLEBORUS. Hellebore.

1. *H. viridis*, green. 3. 200. Chalky woods, rare. Per. 4.
2. *H. fatidus*, stinking. 9. 613. Chalky banks. Per. 3, 4.

CALTHA. Marsh-marigold.

1. *C. palustris*, common. 8. 506. Wet meadows. Per. 5.
2. *C. radicans*, creeping. 31. 2175. Bogs, Scotland. Per. 6.

Class 14. DIDYNAMIA.

Ord. 1. Gymnospermia.

AJUGA. Bugle.

1. *A. reptans*, common. 7. 489. Moist groves. Per. 5.
2. *A. alpina*, alpine. 7. 477. Mountains. Per. 7.
3. *A. pyramidalis*, pyramidal. 18. 1270. Highland hills. Per. 5, 6.
4. *A. Chamæpitys*, ground pine. 2. 77. Sandy fields. Ann. 4, 5.

TEUCRIUM. Germander.

1. *T. Scorodonia*, wood. 22. 1543. Woods and heaths. Per. 7.
2. *T. Scordium*, water. 12. 828. Boggymeadows, rare. Per. 7, 8.
3. *T. Chamædrys*, wall. 10. 680. Old walls. Per. 7.

NEPETA. Cat-mint.

1. *N. cataria*, common. 2. 137. Chalky banks. Per. 7.

VERBENA. Vervain.

1. *V. officinalis*, common. 11. 767. Pastures and rubbish. Per. 7.

MENTHA. Mint.

1. *M. sylvestris*, horse. 10. 686. Moist waste ground. Per. 8, 9.
2. *M. rotundifolia*, round-leaved. 7. 446. Moist ground, rare. Per. 8, 9.
3. *M. viridis*, spear. 34. 2424. Wet meadows. Per. 8.
4. *M. piperita*, pepper. 10. 687. Watery places. Per. 8, 9.
5. *M. odorata*, bergamot. 15. 1025. Wet ground, rare. Per. 7, 8.

6. *M. hirsuta*, hairy. 7. 447, 448, (*fativa*). Watery places. Per. 8, 9.

7. *M. acutifolia*, fragrant sharp-leaved. 34. 2415. River banks, rare. Per. 9.

8. *M. rubra*, tall red. 20. 1413. Wet hedges. Per. 9.

9. *M. gentilis*, bushy red. 30. 2118. Wet waste ground, rare. Per. 8.

10. *M. gracilis*, narrow-leaved. 7. 449, (*gentilis*). Waste ground. Per. 8.

11. *M. arvensis*, corn. 30. 2119. Wet corn-fields. Per. 6-9.

12. *M. agrestis*, rugged field. 30. 2120. Fields. Per. 8.

13. *M. Pulegium*, penny-royal. 15. 1026. Watery pastures. Per. 9.

GLECHOMA. Ground-ivy.

1. *G. hederacea*, common. 12. 853. Woods and hedges. Per. 4, 5.

LAMIUM. Dead-nettle.

1. *L. album*, white. 11. 768. Waste ground. Per. 5-9.

2. *L. maculatum*, spotted. 36. 2550. Banks, rare. Per. 4.

3. *L. purpureum*, red. 11. 769. Waste and cultivated ground. Ann. 5-9.

4. *L. incisum*, cut-leaved. 27. 1933. Sandy fields. Ann. 5.

5. *L. amplexicaule*, henbit. 11. 770. Sandy fields. Ann. 2-6.

GALEOPSIS. Hemp-nettle.

1. *G. Ladanum*, red. 13. 884. Chalky fields. Ann. 8, 9.

2. *G. villosa*, downy. 33. 2353. Sandy fields, rare. Ann. 7, 8.

3. *G. Tetrabit*, common. 3. 207. Corn-fields. Ann. 7, 8.

4. *G. versicolor*, large-flowered. 10. 667. Sandy fields. Ann. 7, 8.

GALEOBOLON. Weasel-snout.

1. *G. luteum*, yellow. 11. 787. Moist groves. Per. 5.

BETONICA. Betony.

1. *B. officinalis*, wood. 16. 1142. Woods and thickets. Per. 7, 8.

STACHYS. Wound-wort.

1. *S. sylvatica*, hedge. 6. 416. Hedges and groves. Per. 7, 8.

2. *S. ambigua*, ambiguous. 30. 2089. North of Scotland. Per. 9.

3. *S. palustris*, marsh. 24. 1675. Wet meadows. Per. 8.

4. *S. germanica*, downy. 12. 829. Chalky fields. Per. 7.

5. *S. arvensis*, corn. 17. 1154. Gravelly fields. Ann. 7, 8.

BALLOTA. Black-horehound.

1. *B. nigra*, stinking. 1. 46. Hedges and rubbish. Per. 7, 8.

MARRUBIUM. White-horehound.

1. *M. vulgare*, aromatic. 6. 410. Dry waste ground. Per. 7.

LEONURUS. Motherwort.

1. *L. Cardiaca*, common. 4. 286. Gravelly banks. Per. 7, 8.

CLINPODIUM. Basil.

1. *C. vulgare*, wild. 20. 1401. Gravelly or chalky banks. Per. 8.

ORIGANUM

PLANTS.

ORIGANUM. Marjoram.

1. *O. vulgare*, common. 16. 1143. Calcareous thickets. Per. 7, 8.

THYMUS. Thyme.

1. *T. Serpyllum*, wild. 22. 1514. Heaths and hills. Per. 7, 8.
2. *T. Acinos*, bafil. 6. 411. Sandy fields. Ann. 7, 8.
3. *T. Calamintba*, common calamint. 24. 1676. Gravelly banks. Per. 7, 8.
4. *T. Nepeta*, lesser calamint. 20. 1414. Chalky banks. Per. 8.

MELITTIS. Baitard-balm.

1. *M. Melissophyllum*, reddish. 9. 577. Woods, west of England. Per. 5, 6.
2. *M. grandiflora*, purple and white. 9. 636. Woods, west of England. Per. 5.

SCUTELLARIA. Scull-cap.

1. *S. galericulata*, common. 8. 523. Watery places. Per. 7, 8.
2. *S. minor*, lesser. 8. 524. Wet gravelly heaths. Per. 8.

PRUNELLA. Self-heal.

1. *P. vulgaris*, common. 14. 961. Meadows and pastures. Per. 7, 8.

Ord. 2. Angiospermia.

BARTSIA. Bartfia.

1. *B. alpina*, alpine purple. 6. 361. Alpine rills. Per. 7.
2. *B. viscosa*, yellow viscid. 15. 1045. Marshes, rare. Ann. 7, 8.
3. *B. Odontites*, red. 20. 1415. Meadows and pastures. Ann. 7, 8.

RHINANTHUS. Yellow-rattle.

1. *R. Crista-galli*, common. 10. 657. Meadows. Ann. 6.

EUPHRASIA. Eye-bright.

1. *E. officinalis*, common. 20. 1416. Heaths and pastures. Ann. 7—9.

MELAMPYRUM. Cow-wheat.

1. *M. cristatum*, crested. 1. 41. Fields and groves, rare. Ann. 7.
2. *M. arvense*, purple. 1. 53. Wheat fields, Norfolk. Ann. 7.
3. *M. pratense*, common. 2. 113. Groves and thickets. Ann. 7, 8.
4. *M. sylvaticum*, wood. 12. 804. Alpine woods. Ann. 7, 8.

LATHRÆA. Tooth-wort.

1. *L. Squamaria*, greater. 1. 50. Dry woods. Per. 4.

PEDICULARIS. Loufe-wort.

1. *P. palustris*, marsh. 6. 399. Marshy meadows. Per. 6, 7.
2. *P. sylvatica*, pasture. 6. 400. Mountain heaths. Per. 6, 7.

ANTIRRHINUM. Snapdragon.

- *1. *A. Cymbalaria*, ivy-leaved. 7. 502. Old walls. Per. 5—11.
2. *A. spurium*, round-leaved fluellin. 10. 691. Fields. Ann. 7—9.

3. *A. Blatine*, sharp-pointed fluellin. 10. 692. Fields. Ann. 7—9.
4. *A. repens*, creeping pale-blue toadflax. 18. 1253. Chalky hills. Per. 7—9.
5. *A. Linaria*, common yellow toadflax. 10. 658. Hedges, &c. Per. 6, 7.
β, with regular pentandrous flowers. 4. 260. See PELORIA.
6. *A. minus*, least. 28. 2014. Sandy fields. Ann. 6—8.
- *7. *A. majus*, great. 2. 129. Old walls. Per. 7, 8.
8. *A. Orontium*, lesser. 17. 1155. Sandy or chalky fields. Ann. 7, 8.

SCROPHULARIA. Figwort.

1. *S. nodosa*, knotty-rooted. 22. 1544. Woods and hedges. Per. 7.
2. *S. aquatica*, water. 12. 854. Watery places. Per. 7.
3. *S. Scorodonia*, balm-leaved. 31. 2209. Wet hedges, rare. Per. 7, 8.
4. *S. vernalis*, yellow. 8. 567. Lanes and hedges, rare. Bienn. 4, 5.

DIGITALIS. Fox-glove.

1. *D. purpurea*, purple. 19. 1297. Pastures and thickets. Bienn. 6, 7.

LINNEA. Linnea.

1. *L. borealis*, two-flowered. 7. 433. Stony woods, Scotland, rare. Per. 6.

SIBTHORPIA. Sibthorpia.

1. *S. europea*, Cornish moneywort. 10. 649. Moist ground, Cornwall. Per. 7, 8.

LIMOSELLA. Mud-wort.

1. *L. aquatica*, little. 5. 357. Muddy ground. Ann. 7, 8.

OROBANCHE. Broom-rape.

1. *O. major*, greater. 6. 421. On broom or furze. Per. 6, 7.
2. *O. elatior*, tall. 8. 568. On various roots. Per. 7, 8.
3. *O. minor*, lesser. 6. 422. On clover roots. Ann. 7, 8.
4. *O. rubra*, red fragrant. 25. 1786. Basaltic rocks, Ireland. Per. 8.
5. *O. cœrulea*, purple. 6. 423. Pastures near the sea. Per. 7.
6. *O. ramosa*, branched. 3. 184. On hemp. Ann. 8, 9.

Class 15. TETRADYNAMIA.

Ord. 1. Siliculosa.

VFLLA. Cress-rocket.

1. *V. annua*, annual. 21. 1442. Sandy fields, rare. Ann. 6.

SUBULARIA. Awl-wort.

1. *S. aquatica*, water. 11. 732. In alpine lakes. Ann. 7.

DRABA. Whitlow-grass.

1. *D. verna*, common. 9. 586. Walls and pastures. Ann. 3, 4.
2. *D. aizoides*, yellow alpine. 18. 1271. Rocks, South Wales. Per. 3.
3. *D. hirta*, simple-haired. 19. 1338. Alpine rocks. Per. 5, 6.

PLANTS.

4. *D. incana*, twisted-podded. 6. 388. Limestone rocks. Bienn. 5, 6.
 5. *D. muralis*, speedwell-leaved. 13. 912. Shady hills. Ann. 5.

ALYSSUM. Alyffum.

- *1. *A. sativum*, gold of pleasure. 18. 1254. Fields. Ann. 6.
 2. *A. maritimum*, sweet. 25. 1729. Sea-coast, rare. Per. 8, 9.

LEPIDIUM. Pepper-wort.

1. *L. latifolium*, broad-leaved. 3. 182. Sea-coast. Per. 7.
 2. *L. ruderale*, narrow-leaved. 23. 1595. Sea-coast. Bienn. 6.
 3. *L. campestre*, mithridate. 20. 1385. (Thlaspi). Fields, Ann. 7.
 4. *L. hirtum*, hairy. 26. 1803. (Thlaspi). Fields, rare. Per. 6.

HUTCHINSIA. Hutchinsia.

Brown in Ait. Hort. Kew. v. 4. 82.

Eff. Ch. Pouch entire; valves tumid. Seeds two in each cell. Filaments simple.

1. *H. petraea*, rock. 2. 111. (*Lepidium petraeum*). Limestone. Bienn. 3, 4.

Leaves pinnatifid, entire. Petals shorter than the calyx. Stigma sessile.

Named, by Mr. R. Brown, in honour of Miss Hutchins, of Bantry, in Ireland; a lady whose discoveries in the most difficult parts of practical botany, well entitle her to commemoration. The genus is distinguished from *Draba* and *Subularia*, in having but two, instead of many, seeds in each cell; and moreover from the former in having tumid, not nearly flat valves; from the latter in not having linear cotyledons. *Lepidium* has properly an emarginate pouch, with keeled valves, and solitary seeds. Other species of *Hutchinsia* are *Iberis rotundifolia* and *Lepidium alpinum* of Linnæus.

TEESDALIA. Teesdalia.

Brown in Ait. Hort. Kew. v. 4. 83.

Eff. Ch. Pouch emarginate, inversely heart-shaped. Seeds two in each cell. Filaments each bearing a scale, at the inside, near the base.

1. *T. nudicaulis*, naked-stalked. 5. 327. (*Iberis nudicaulis*). Gravelly pastures. Ann. 5.

Petals equal.

This genus is dedicated, by Mr. Brown, to the memory of the late Mr. Robert Teesdale, F.L.S. Another species is the exotic *Lepidium nudicaule* of Linnæus, differing in having equal petals, and but four stamens. See *TEESDALIA* hereafter in its proper place.

THLASPI. Mithridate Mustard.

1. *T. arvense*, penny cress. 24. 1659. Fields, rare. Ann. 6, 7.
 2. *T. perfoliatum*, perfoliate. 33. 2354. Limestone quarries. Ann. 4, 5.
 3. *T. alpestre*, alpine. 2. 81. Limestone hills. Per. 6, 7.
 4. *T. Bursa-pastoris*, shepherd's purse. 21. 1485. Common. Ann. 3—9.

COCHLEARIA. Scurvy-grass.

1. *C. officinalis*, common. 8. 551. Mountains, and sea-coast. Ann. 5.

2. *C. groenlandica*, Greenland. 34. 2403. Highlands. Ann. 8
 3. *C. anglica*, English. 8. 552. Muddy sea shores. Ann. 5.
 4. *C. danica*, Danish. 10. 696. Muddy shores, rare. Ann. 5, 6.
 5. *C. Armoracia*, horse-radish. 33. 2323. Watery places. Per. 5.

CORONOPUS. Wart-cress.

1. *C. Ruellii*, common. 24. 1660. Waste ground. Ann. 6—8.
 2. *C. didyma*, lesser. 4. 248. West of England. Ann. 7.

IBERIS. Candy-tuft.

1. *I. amara*, bitter. 1. 52. Chalky fields, rare. Ann. 7.

ISATIS. Woad.

1. *I. tinctoria*, dyer's. 2. 97. Fields, rare. Bienn. 7.

BUNIAS. Sea Rocket.

1. *B. Cakile*, common. 4. 231. Sandy shore. Ann. 6—9.

CRAMBE. Kale.

1. *C. maritima*, sea. 13. 924. Sandy sea-coast. Per. 5, 6.

Ord. 2. Siliquosa.

DENTARIA. Coral-wort.

1. *D. bulbifera*, bulbiferous. 5. 309. Shady places, rare. Per. 4, 5.

CARDAMINE. Ladies'-smock.

1. *C. bellidifolia*, daisy-leaved. 33. 2355. Mountains, rare. Per. 8.
 2. *C. impatiens*, impatient. 2. 80. Stony mountains. Ann. 5, 6.
 3. *C. hirsuta*, hairy. 7. 492. Waste and cultivated ground. Ann. 3—6.
 4. *C. pratensis*, meadow. 11. 776. Meadows and pastures. Per. 4, 5.
 5. *C. amara*, bitter. 14. 1000. Watery places, rare. Per. 4, 5.

SISYMBRIUM. Rocket.

1. *S. Nasturtium*, water-cress. 12. 855. Running waters. Per. 6, 7.
 2. *S. sylvestre*, creeping water. 33. 2324. Inundated gravel. Per. 6—9.
 3. *S. terrestre*, annual water. 25. 1747. Watery places. Ann. 6—9.
 4. *S. amphibium*, great water. 26. 1840. Rivers. Per. 6—8.
 5. *S. tenuifolium*, greater wall. 8. 525. Walls and rubbish. Per. 7—10.
 6. *S. murale*, spreading wall. 16. 1090. Sandy wastes. Ann. 8—10.
 7. *S. monense*, dwarf sea. 14. 962. Sandy coasts, rare. Per. 6, 7.
 8. *S. Sophia*, flix-weed. 14. 963. Waste ground. Ann. 7.
 9. *S. Irio*, London. 23. 1631. Rubbish and walls. Ann. 7, 8.

ERYSIMUM. Hedge-mustard.

1. *E. officinale*, common. 11. 735. Waste places, and roads. Ann. 6, 7.

PLANTS.

2. *E. Barbarea*, bitter winter-crefs. 7. 443. Rubbifh and ditches. Per. 5—8.
3. *E. praxox*, early winter-crefs. 16. 1129. Watery places. Bienn. 4—10.
4. *E. Alliaria*, garlick. 12. 796. Hedges, common. Bienn. 5.
5. *E. cheiranthoides*, treacle. 14. 942. Fields and willow-beds. Ann. 7.

CHEIRANTHIUS. Stock.

1. *C. fruticulofus*, wall-flower. 27. 1934. Old walls. Per. 5, 6.
2. *C. incanus*, hoary fhubby. 27. 1935. Sea cliffs, rare. Shrubby. 5.
3. *C. finuatus*, fea. 7. 462. Welch coaft. Bienn. 8.

HESPERIS. Dame's-violet.

- † 1. *H. inodora*, fcenblefs. 11. 731. Banks of rivulets, rare. Per. 5, 6.

ARABIS. Wall-crefs.

1. *A. thaliana*, common. 13. 901. Walls and banks. Ann. 4.
2. *A. ftricta*, Bristol rock. 9. 614. Rocks, Bristol. Per. 5.
3. *A. hispida*, alpine rock. 7. 469. (Cardamine haftulata). Rocks. Per. 6, 7.
4. *A. Turritia*, tower. 3. 178. Walls, rare. Bienn. 5.

TURRITIS. Tower-muftard.

1. *T. glabra*, fsmooth. 11. 777. Gravelly banks. Ann. 5, 6.
2. *T. hirsuta*, hairy. 9. 587. Rocks and walls. Per. 5.
3. *T. alpina*, alpine. 25. 1746. Weft of Ireland. Bienn. 7.

BRASSICA. Cabbage.

1. *B. orientalis*, perfoliate. 26. 1804. Fields and cliffs. Ann. 6.
2. *B. campeftris*, field. 32. 2234. Fields. Ann. 6.
3. *B. Napus*, rape, or navev. 30. 2146. Fields and banks. Bienn. 5.
4. *B. Rapa*, turnep. 31. 2176. Fields. Bienn. 4.
5. *B. oleracea*, fea. 9. 637. Sea cliffs. Bienn. 5, 6.

SINAPIS. Muftard.

1. *S. arvensis*, charlock. 25. 1748. Fields, common. Ann. 5.
2. *S. alba*, white. 24. 1677. Fields. Ann. 6.
3. *S. nigra*, common. 14. 969. Fields and banks. Ann. 6.

RAPHANUS. Radifh.

1. *R. Raphaniftrum*, wild. 12. 856. Corn-fields. Ann. 6, 7.
2. *R. maritimus*, fea. 23. 1643. Sea-coaft. Bienn. 6.

Clafs 16. MONADELPHIA.

Ord. 1. Pentandria.

ERODIUM. Stork's-bill.

1. *E. cicutarium*, hemlock. 25. 1768. Rubbifh and fand. Ann. 6—8.

VOL. XXVII.

2. *E. moschatum*, mufty. 13. 902. Mountain paftures. Ann. 6, 7.
3. *E. maritimum*, fea. 9. 646. Sandy coaft. Per. 5—9.

Ord. 2. Decandria.

GERANIUM. Crane's-bill.

1. *G. pheaum*, dufty. 5. 322. Mountain thickets. Per. 5, 6.
2. *G. nodofum*, knotty. 16. 1091. Mountains, rare. Per. 5—8.
3. *G. fylvaticum*, wood. 2. 121. Mountain thickets. Per. 6, 7.
4. *G. pratense*, crowfoot-leaved. 6. 404. Hilly paftures. Per. 6, 7.
5. *G. robertianum*, ftinking. 21. 1486. Rubbifh and banks. Ann. 5—10.
6. *G. lucidum*, fhining. 2. 75. Walls and ftony places. Ann. 5—8.
7. *G. molle*, dove's-foot. 11. 778. Paftures and rubbifh. Ann. 4—8.
8. *G. pufillum*, fmall-flowered. 6. 385. Gravelly ground. Ann. 6—9.
9. *G. pyrenaicum*, mountain. 6. 405. Meadows and paftures. Per. 7.
10. *G. rotundifolium*, round-leaved. 3. 157. Gravelly banks. Ann. 6, 7.
11. *G. diffeetum*, jagged-leaved. 11. 753. Barren banks. Ann. 5, 6.
12. *G. columbinum*, long-ftalked. 4. 259. Chalky banks. Ann. 6, 7.
13. *G. fanguineum*, bloody. 4. 272. Rocks and hills. Per. 7—9.

Ord. 3. Polyandria.

ALTHÆA. Marsh-mallow.

1. *A. officinalis*, common. 3. 147. Sea marfhes. Per. 7—9.

MALVA. Mallow.

1. *M. fylveftris*, common. 10. 671. Hedges and rubbifh. Per. 5—8.
2. *M. rotundifolia*, dwarf. 16. 1092. β. 4. 241. Rubbifh. Ann. 6—9.
3. *M. moschata*, mufk. 11. 754. Gravelly banks. Per. 7, 8.

LAVATERA. Tree-mallow.

1. *L. arborea*, fea. 26. 1841. Sea-coaft, rare. Bienn. 7—10.

Clafs 17. DIADELPHIA.

Ord. 1. Hexandria.

FUMARIA. Fumitory.

1. *F. folida*, folid bulbous. 21. 1471. Northern woods. Per. 4, 5.
2. *F. lutea*, yellow. 9. 588. Old walls. Per. 5.
3. *F. officinalis*, common. 9. 589. Cultivated ground. Ann. 5—8.
4. *F. parvijflora*, fmall-flowered. 9. 590. Fields, in the fouth. Ann. 8, 9.
5. *F. capreolata*, ramping. 14. 943. Fields, rare. Ann. 6—9.
6. *F. claviculata*, white climbing. 2. 103. Gravelly thickets. Ann. 6, 7.

4 N

Ord. 2.

PLANTS.

Ord. 2. *Oxandria*.

POLYGALA. Milkwort.

1. *P. vulgaris*, common. 2. 76. Sunny pastures. Per. 6, 7.

Ord. 3. *Decandria*.

SPARTIUM. Broom.

1. *S. scoparium*, common. 19. 1339. Dry hills and fields. Shrub. 5, 6.

GENISTA. Green-weed.

1. *G. tinctoria*, dyer's. 1. 44. Pastures and thickets. Shrub. 7, 8.
 2. *G. pilosa*, hairy. 3. 208. Barren heaths, rare. Shrubby. 5.
 3. *G. anglica*, needle. 2. 132. Moist heaths. Low shrub. 5, 6.

ULEX. Furze.

1. *U. europaeus*, common. 11. 742. Heaths and sandy downs. Shrub. 5—12.
 2. *U. nanus*, dwarf. 11. 743. Elevated heaths. Shrub. 8—10.

ONONIS. Rest-harrow.

1. *O. arvensis*, common. 10. 682. Barren pastures, &c. Per. 6—8.

ANTHYLLIS. Kidney-vetch.

1. *A. vulneraria*, ladies'-finger. 2. 104. Chalky hills. Per. 6—8.

PISUM. Pea.

1. *P. maritimum*, pea. 15. 1046. Stony sea beach. Per. 7.

OROBUS. Bitter-vetch.

1. *O. tuberosus*, heath. 17. 1153. Heaths and thickets. Per. 5, 6.
 2. *O. sylvaticus*, wood. 8. 518. Mountain woods. Per. 5, 6.

LATHYRUS. Lathyrus.

1. *L. Aphaca*, yellow vetchling. 17. 1167. Gravelly banks, rare. Ann. 6—8.
 2. *L. Nissolia*, crimson grassy. 2. 112. Bushy places. Ann. 5.
 3. *L. hirsutus*, rough-podded. 18. 1255. Fields, rare. Ann. 7.
 4. *L. pratensis*, yellow meadow. 10. 670. Meadows and pastures. Per. 7, 8.
 5. *L. sylvestris*, narrow-leaved. 12. 805. Moist thickets. Per. 7, 8.
 6. *L. latifolius*, broad-leaved. 16. 1108. Woods, rare. Per. 7, 8.
 7. *L. palustris*, marsh. 3. 169. Wet thickets. Per. 7, 8.

VICIA. Vetch.

1. *V. sylvatica*, wood. 2. 79. Mountain thickets. Per. 7, 8.
 2. *V. Cracca*, tufted. 17. 1168. Meadows and hedges. Per. 7, 8.
 3. *V. sativa*, common. 5. 334. Fields and grassy places. Ann. 5, 6.
 4. *V. lathyroides*, spring. 1. 30. Gravelly fields. Ann. 4, 5.
 5. *V. lutea*, rough-podded yellow. 7. 481. Stony beach. Per. 8.

6. *V. hybrida*, hairy-flowered yellow. 7. 482. Thickets, rare. Per. 6.

7. *V. levigata*, smooth-podded pea. 7. 483. Stony beach, rare. Per. 8.

8. *V. sepium*, bush. 22. 1515. Bushy places, common. Per. 5, 6.

9. *V. bithynica*, rough-podded purple. 26. 1842. Pastures, rare. Per. 7, 8.

ERVUM. Tare.

1. *E. tetraspermum*, smooth. 17. 1223. Moist fields. Ann. 6.

2. *E. hirsutum*, hairy. 14. 970. Fields and meadows. Ann. 6.

ORNITHOPUS. Bird's-foot.

1. *O. perpusillus*, common. 6. 369. Gravel or sand. Ann. 5.

HIPPOCREPIS. Horfe-shoe-vetch.

1. *H. comosa*, tufted. 1. 31. Chalky hills. Per. 5—8.

HEDYSARUM. Saint-foin.

1. *H. Onobrychis*, common. 2. 96. Chalky hills. Per. 6, 7.

ASTRAGALUS. Milk-vetch.

1. *A. glycyphyllos*, sweet. 3. 203. Chalky thickets. Per. 6.

2. *A. hypoglottis*, purple mountain. 4. 274. Chalk or sand. Per. 6, 7.

3. *A. uralensis*, hairy mountain. 7. 466. Scottish hills. Per. 7.

4. *A. campestris*, yellowish mountain. 36. 2522. Highlands. Per. 7.

TRIFOLIUM. Trefoil.

1. *T. officinale*, melilot. 19. 1340. Bushy places. Ann. 6, 7.

2. *T. ornithopodioides*, bird's-foot. 15. 1047. Gravelly heaths. Ann. 6, 7.

3. *T. repens*, white clover. 25. 1769. Meadows, common. Per. 5—9.

4. *T. subterraneum*, subterranean. 15. 1048. Gravelly pastures. Ann. 5.

5. *T. ochroleucum*, sulphur-coloured. 17. 1224. Dry pastures. Per. 6, 7.

6. *T. pratense*, common purple clover. 25. 1770. Meadows and pastures. Per. 5—9.

7. *T. medium*, zigzag. 3. 190. Chalky or gravelly pastures. Per. 7.

8. *T. maritimum*, teal-headed. 4. 220. Muddy sea shore. Ann. 6, 7.

9. *T. stellatum*, starry-headed. 22. 1545. South coast. Ann. 7.

10. *T. arvense*, hare's-foot. 14. 944. Sandy fields. Ann. 7, 8.

11. *T. scabrum*, rough. 13. 903. Chalk or sand. Ann. 5, 6.

12. *T. glomeratum*, round-headed. 15. 1063. Gravelly pastures. Ann. 6.

13. *T. striatum*, soft knotted. 26. 1843. Barren ground. Ann. 6.

14. *T. suffocatum*, suffocated. 15. 1049. Sea sand. Ann. 6, 7.

15. *T. fragiferum*, strawberry-headed. 15. 1050. Moist pastures. Per. 7, 8.

16. *T. procumbens*, hop. 14. 945. Dry gravelly pastures. Ann. 6, 7.

PLANTS.

17. *T. minus*, leffer yellow. 18. 1256. Gravelly ground. Ann. 6, 7.
 18. *T. filiforme*, slender yellow. 18. 1257. Moist gravel. Ann. 6, 7.

LOTUS. Bird's-foot Trefoil.

1. *L. corniculatus*, common. 30. 2090. Pastures, common. Per. 6—8.
 2. *L. major*, greater. 30. 2091. Wet bushy places. Per. 7, 8.
 3. *L. diffusus*, slender. 13. 925. Rocks, fourth coast. Per? 5, 6.

MEDICAGO. Medick.

- *1. *M. sativa*, purple, or lucerne. 25. 1749. Meadows and pastures. Per. 6, 7.
 2. *M. falcata*, yellow. 15. 1016. Gravelly and chalky banks. Per. 7.
 3. *M. lupulina*, black. 14. 971. Meadows and pastures. Ann. 5—8.
 4. *M. maculata*, spotted. 23. 1616 (polymorpha). Gravelly banks. Ann. 5, 6.
 5. *M. muricata*, flat-toothed. Pluk. Phyt. t. 113. f. 6. Suffolk coast. Ann. 6.
 6. *M. minima*, little bur. Fl. Dan. t. 211. Chalky ground. Ann. 6.

Class 18. POLYADELPHIA.

Ord. 1. Polyandria.

HYPERICUM. St. John's-wort.

1. *H. calycinum*, large-flowered. 29. 2017. Thickets, Ireland. Shrubby. 7—9.
 2. *H. Androsæmum*, tutfan. 18. 1225. Woods, rare. Per. 7, 8.
 3. *H. quadrangulum*, square. 6. 370. Moist meadows. Per. 7, 8.
 4. *H. perforatum*, perforated. 5. 295. Bushy places. Per. 7, 8.
 5. *H. dubium*, imperforate. 5. 296. Mountain thickets. Per. 7, 8.
 6. *H. humifusum*, trailing. 18. 1226. Pastures and groves. Per. 7.
 7. *H. montanum*, mountain. 6. 371. Bushy hills. Per. 7.
 8. *H. barbatum*, bearded. 28. 1986. Thickets, Scotland. Per. 9, 10.
 9. *H. hirsutum*, hairy. 17. 1156. Chalky banks. Per. 6, 7.
 10. *H. pulchrum*, small upright. 18. 1227. Clay heaths. Per. 7.
 11. *H. elodes*, marsh. 2. 109. Spongy bogs. Per. 7, 8.

Class 19. SYNGENESIA.

Ord. 1. Polygamia æqualis.

TRAGOPOGON. Goat's-beard.

1. *T. pratensis*, yellow. 7. 434. Grassy pastures. Bienn. 6.
 2. *T. porrifolius*, purple. 9. 638. Moist meadows, rare. Bienn. 5, 6.

PICRIS. Ox-tongue.

1. *P. echioides*, brittle. 14. 972. Clay pastures and banks. Ann. 6, 7.

2. *P. hieracioides*, hawkweed. 3. 196. Gravel or chalk. Bienn. 7, 8.

SONCHUS. Sow-thistle.

1. *S. ceruleus*, blue. 34. 2425. Highland pastures, rare. Per. 7, 8.
 2. *S. palustris*, tall marsh. 13. 935. Banks of rivers. Per. 7, 8.
 3. *S. arvensis*, corn. 10. 674. Corn-fields, on clay. Per. 8.
 4. *S. oleraceus*, common. 12. 843. Fields, banks, and rubbish. Ann. 7—9.

LACTUCA. Lettuce.

1. *L. virofa*, strong-scented. 28. 1957. Chalky banks. Bienn. 8, 9.
 2. *L. Scariola*, prickly. 4. 268. Rubbish, rare. Bienn. 8.
 3. *L. faligna*, leaf. 10. 707. Chalky banks. Bienn. 8.

PRENANTHES. Wall-Lettuce.

1. *P. muralis*, ivy-leaved. 7. 457. Walls, or chalky groves. Per. 7.

LEONTODON. Dandelion.

1. *L. Taraxacum*, common. 8. 510. Meadows and pastures. Per. 4—7.
 2. *L. palustre*, marsh. 8. 553. Moist meadows. Per. 6, 7.

APARGIA. Hawkbit.

Schreb. 527. *Willd. Sp. Pl.* v. 3. 1547. *Sm. Prodr. Fl. Græc. Sibth.* v. 2. 130. *Ait. Hort. Kew.* v. 4. 445.
Hedynois; *Hudf.* 340. *Sm. Fl. Brit.* 823.

Ess. Ch. Receptacle naked, dotted. Calyx imbricated. Seed-down feathery, sessile, unequal.

1. *A. hispida*, rough. 8. 554. (*Hedynois hispida*). Chalky pastures. Per. 7.
 Stalks radical, single-flowered. Leaves toothed, rough. Florets hairy at the orifice, glandular at the extremity.

2. *A. hirta*, deficient. 8. 555. (*H. hirta*). Gravelly pastures. Per. 7, 8.

Stalks radical, single-flowered. Leaves toothed, rough. Calyx nearly smooth. Outer row of seeds naked.

3. *A. Taraxici*, alpine. 16. 1109. (*H. Taraxici*). Alpine hills. Per. 8.

Stalks radical, mostly single-flowered. Leaves with reversed teeth, smooth. Calyx hairy.

4. *A. autumnalis*, autumnal. 12. 830. (*H. autumnalis*). Pastures. Per. 8.

Stalk radical, branched; subdivisions scaly. Leaves lanceolate, smoothish; toothed or pinnatifid.

Willdenow has, in all, 17 species of this genus, among which are *Leontodon alpinum*, Jacq. Aufr. t. 93; *L. hastile*, Linn. Sp. Pl. 1123; *L. tuberosum*, ibid: *Hieracium incanum*, Jacq. Aufr. t. 287; *Leontodon crispum*, Villars Dauph. v. 3. 84. t. 25; *L. coronopifolium*, Desfont. Atlant. v. 2. 229. t. 214; and *L. hispidum*, Cavan. Ic. t. 149; the latter named *Apargia hispanica*, Willd. n. 14. See HEDYNOIS.

HIERACIUM. Hawkweed.

1. *H. alpinum*, alpine single-flowered. 16. 1110. Alpine rocks. Per. 7.

2. *H. Pilosella*, moufe-ear. 16. 1093. Pastures and walls. Per. 5—7.

3. *H. dubium*, branching moufe-ear. 33. 2332. Hills, rare. Per. 7, 8.

†4. *H. Auricula*, orange moufe-ear. 33. 2368. Mountains? Per. 7, 8.

PLANTS.

5. *H. aurantiacum*, great orange. 21. 1469. Woods, Scotland. Per. 6, 7.
6. *H. murorum*, wall. 29. 2082. Rocks and walls. Per. 6.
7. *H. maculatum*, stained-leaved. 30. 2121. Mountain rocks. Per. 6.
8. *H. sylvaticum*, wood. 29. 2031. Rocks and walls, common. Per. 6, 7.
9. *H. pulmonarium*, lungwort. 33. 2307. Rocks, Scotland. Per. 7.
10. *H. Lacusoni*, glaucous hairy. 29. 2083. North of England. Per. 7.
11. *H. pulchellum*, fucory-leaved mountain. 16. 1094. Mountain hills. Per. 7.
12. *H. molle*, soft-leaved. 31. 2210. Woods, Scotland. Per. 7, 8.
13. *H. cerinthoides*, honeywort-leaved. 34. 2378. Rocks, Scotland. Per. 8.
14. *H. villosum*, shaggy alpine. 34. 2379. Highlands. Per. 8.
15. *H. sabaudum*, shrubby broad-leaved. 5. 349. Groves. Per. 8, 9.
16. *H. denticulatum*, small-toothed. 30. 2122. Woods, Scotland. Per. 8, 9.
17. *H. prenanthoides*, rough-bordered. 32. 2235. Woods, Scotland. Per. 8.
18. *H. umbellatum*, narrow-leaved. 25. 1771. Stony groves. Per. 8, 9.

CREPIS. Hawk's-beard.

1. *C. fatida*, stinking. 4. 406. Chalky pastures, rare. Bienn. 6, 7.
2. *C. pulchra*, small-flowered. 33. 2325. Rocks, Scotland. Ann. 6—9.
3. *C. tetorum*, smooth. 16. 1111. Pastures and rubbish. Ann. 6—9.
4. *C. biennis*, rough. 3. 149. Chalky pastures. Bienn. 6, 7.

HYPOCHÆRIS. Cat's-ear.

1. *H. maculata*, spotted. 4. 225. Chalky downs. Per. 7.
2. *H. glabra*, smooth. 8. 575. Gravelly fields. Ann. 6—8.
3. *H. radicata*, long-rooted. 12. 831. Meadows and pastures. Per. 6—8.

LAPSANA. Nipple-wort.

1. *L. communis*, common. 12. 844. Fields and rubbish. Ann. 6, 7.
2. *L. pusilla*, little. 2. 95. (*Hyoferis minima*). Gravelly fields. Ann. 6.

Stem none. Stalks subdivided; swelling and hollow at the summit. Leaves obovate. The seeds have an elevated border, which is unlike the true *Lapsana*, but this plant is perhaps better placed here than elsewhere. See LAPSANA.

CICORIUM. Succory.

1. *C. Intybus*, wild. 8. 539. Gravel or chalk. Per. 7, 8.

ARCTIUM. Bur-dock.

1. *A. Lappa*, common. 18. 1228. Waste places. Bienn. 7, 8.
2. *A. Bardana*, woolly-headed. 35. 2478. Waste hilly ground. Bienn. 7, 8.

SERRATULA. Saw-wort.

1. *S. tinctoria*, common. 1. 38. Groves and thickets. Per. 7, 8.
2. *S. alpina*, alpine. 9. 599. Alpine rocks. Per. 7, 8.

CARDUUS. Thistle.

1. *C. nutans*, musk. 16. 1112. Gravelly or chalky fields. Ann. 7, 8.
2. *C. acanthoides*, curled or watted. 14. 973. Waste ground. Ann. 6, 7.
3. *C. tenuiflorus*, slender-flowered. 6. 412. Banks, rare. Ann. 6, 7.
4. *C. marianus*, milk. 14. 976. Banks and hedges. Ann. 8.

CNICUS. Plume-thistle.

1. *C. lanceolatus*, spear. 2. 107. (*Carduus lanceolatus*). Banks. Bienn. 6—9.
2. *C. palustris*, marsh. 14. 974. (*Card. palustris*). Moist pastures. Bienn. 7, 8.
3. *C. arvensis*, creeping. 14. 975. (*Card. arvensis*). Fields and roads. Per. 7.
4. *C. eriophorus*, woolly-headed. 6. 386. (*Card. erioph.*) Chalk or gravel. Bienn. 8.
5. *C. tuberosus*, tuberous. 36. 2562. Woods, Wiltshire. Per. 8.
6. *C. heterophyllus*, melancholy. 10. 675 (*Card. neteroph.*) Mountain pastures. Per. 7, 8.
7. *C. pratensis*, meadow. 3. 177 (*Card. prat.*) Moist pastures. Per. 6.
8. *C. acaulis*, dwarf. 3. 161 (*Card. acaulis*). Gravel or chalk. Per. 7, 8.

ONOPORDUM. Cotton-thistle.

1. *O. Acanthium*, common. 14. 977. Gravelly banks. Bienn. 7.

CARLINA. Carline-thistle.

1. *C. vulgaris*, common. 16. 1144. Dry sandy fields. Bienn. 6.

BIDENS. Bur-marygold.

1. *B. tripartita*, trifid. 16. 1113. Ditches and puddles. Ann. 8, 9.
2. *B. cernua*, nodding. 16. 1114. Watery places. Ann. 9.

EUPATORIUM. Hemp-agrimony.

1. *E. cannabinum*, common. 6. 428. Watery boggy places. Per. 7, 8.

CHRYSOCEMA. Goldy-locks.

1. *C. Linosyris*, flax-leaved. 35. 2505. Sea cliffs, Devonshire. Per. 9.

SANTOLINA. Cotton-weed.

1. *S. maritima*, sea. 2. 141. Sandy beach, rare. Per. 8, 9.

Ord. 2. *Polygamia-superflua*.

TANACETUM. Tanfy.

1. *T. vulgare*, common. 18. 1229. Hills and way sides. Per. 7, 8.

ARTEMISIA.

PLANTS.

ARTEMISIA. Mugwort.

1. *A. campestris*, field fouthernwood. 5. 338. Sandy fields, rare. Per. 8.
2. *A. maritima*, drooping fea wormwood. 24. 1706. Muddy fea shore. Per. 8.
3. *A. gallica*, upright fea wormwood. 14. 1001 (*maritima*). Muddy shores. Per. 8. Radical leaves capillary. Clusters erect.
4. *A. Absinthium*, common wormwood. 18. 1230. Rubbifh. Per. 8.
5. *A. vulgaris*, common. 14. 978. Waste ground, hedges, &c. Per. 8.
- †6. *A. cerulefcens*, blueifh. 34. 2426. Sea shore, Lincolnfhire. *Hudfon*. Per. 8.

GNAPHALIUM. Cudweed.

1. *G. luteo-album*, Jerfey. 14. 1002. Sandy ground, Jerfey. Ann. 7, 8.
2. *G. margaritaceum*, American. 29. 2018. Meadows, rare. Per. 8.
3. *G. dioicum*, mountain. 4. 267. Dry mountain pafures. Per. 6, 7.
4. *G. fylvaticum*, Highland. 13. 913. Alpine pafures. Per. 8.
5. *G. reatum*, upright wood. 2. 124. Sandy thickets. Per. 8.
6. *G. fupinum*, dwarf. 17. 1193. Micaceous mountains. Per. 7.
7. *G. uliginofum*, marfh. 17. 1194. Sandy puddles. Ann. 8.
8. *G. gallicum*, narrow-leaved. 33. 2369. Gravelly fields, rare. Ann. 7, 8.
9. *G. minimum*, leaf. 17. 1157. Barren gravelly fields. Ann. 7.
10. *G. germanicum*, common. 14. 946. Gravelly fields. Ann. 7, 8.

CONYZA. Spikenard.

1. *C. fquarrefa*, plowman's. 17. 1195. Calcareous pafures. Bienn. 7, 8.

ERIGERON. Flea-bane.

- *1. *E. canadefe*, Canada. 29. 2019. Fields and rubbifh. Ann. 8, 9.
 2. *E. acre*, blue. 17. 1158. Dry gravelly ground. Bienn. 7, 8.
 3. *E. alpinum*, alpine. 7. 464. Alpine rills, Scotland. Per. 7.
 4. *E. uniflorum*, pale mountain. 34. 2416. Highlands. Per. 7.
- Stems mottly fingle-flowered. Calyx hairy. Florets of the radius erect, fomewhat tubular.

TUSSILAGO. Colt's-foot.

1. *T. Farfara*, common. 6. 429. Moift chalk. Per. 3, 4.
2. *T. hybrida*, tall butter-bur. 6. 430. Moift meadows, rare. Per. 4.
3. *T. Petafites*, common butter-bur. 6. 431. Moift meadows. Per. 4.

SENECIO. Ragwort.

1. *S. vulgaris*, common groundfel. 11. 747. Fields and rubbifh. Ann. 3—10.
2. *S. vilcofus*, ftinking. 1. 32. Chalky banks, rare. Ann. 7—10.

3. *S. lividus*, green-fcaled. 35. 2515. Barren heaths. Ann. 9, 10.
4. *S. fylvaticus*, mountain. 11. 748. Gravelly thickets. Ann. 7, 8.
5. *S. fqualidus*, inelegant. 9. 600. Walls, Oxford. Ann. 6—10.
6. *S. tenuifolius*, hoary. 8. 574. Chalky hedges. Per. 7, 8.
7. *S. Jacobea*, common. 16. 1130. Pafures and meadows. Per. 7, 8.
8. *S. aquaticus*, marfh. 16. 1131. Marfhes. Per. 7, 8.
9. *S. puludofus*, fen. 10. 650. Fens, rare. Per. 6, 7.
10. *S. faracenicus*, broad-leaved. 31. 2211. Moift hills. Per. 7, 8.

ASTER. Star-wort.

1. *A. Tripolium*, fea. 2. 87. Muddy fea ditches. Per. 8, 9.

SOLIDAGO. Golden-rod.

1. *S. Virgaurea*, common. 5. 301. Groves and heaths. Per. 7—9.

INULA. Inula.

1. *I. Helenium*, elecampane. 22. 1546. Moift pafures, rare. Per. 7, 8.
2. *I. dyfenterica*, common fleabane. 16. 1115. Watery places. Per. 8.
3. *I. pulicaria*, fmall fleabane. 17. 1196. Sandy puddles. Ann. 9.
4. *I. crithmoides*, famphire-leaved. 1. 68. Muddy falt-marfhes. Per. 8.

CINERARIA. Flea-wort.

1. *C. paluftris*, marfh. 3. 151. Ditches and bogs. Per. 6, 7.
2. *C. integrifolia*, mountain. 3. 152. Chalky hills. Per. 5—7.

DORONICUM. Leopard's-bane.

1. *D. Pardalianches*, great. 9. 630. Mountain pafures, rare. Per. 5.

BELLIS. Daify.

1. *B. perennis*, common. 6. 424. Pafures. Per. 3—12.

CHRYSANthemum. Ox-eye.

1. *C. Leucanthemum*, great white. 9. 601. Pafures and fields. Per. 6, 7.
2. *C. fegetum*, yellow corn. 8. 540. Cultivated fields. Ann. 6—8.

PYRETHRUM. Feverfew.

1. *P. Parthenium*, common. 18. 1231. Rubbifh. Per. 6, 7.
2. *P. inodorum*, corn. 10. 676. Gravelly fields. Ann. 8, 9.
3. *P. maritimum*, fea. 14. 979. Sea-coaft, rare. Per. 7.

MATRICARIA. May-weed.

1. *M. Chamomilla*, wild chamomile. 18. 1232. Fields and dunghills. Ann. 5—7.

ANTHEMIS. Chamomile.

1. *A. maritima*, fea. 33. 2370. Stony beach, rare. Ann. 7.
2. *A. nobilis*, common. 14. 980. Gravelly pafures. Per. 8, 9.

PLANTS.

3. *A. arvensis*, corn. 9. 602. Gravelly fields. Ann. or Bienn. 6, 7.
4. *A. Cotula*, stinking. 25. 1772. Fields, common. Ann. 6, 7.
5. *A. tinctoria*, ox-eye. 21. 1472. Stony banks, rare. Per. 7, 8.

ACHILLEA. Yarrow.

1. *A. Ptarmica*, goose-tongue. 11. 757. Moist bushy places. Per. 7, 8.
2. *A. ferrata*, ferrated. 36. 2531. Derbyshire. Per. 8. Leaves linear-lanceolate, sessile, downy, deeply ferrated; lacinated at the base. Corymbs nearly simple. Fragrant; the flowers smaller than those of *Ptarmica*, and yellowish.
3. *A. Millefolium*, common. 11. 758. Pastures, common. Per. 6—8.
4. *A. tomentosa*, woolly yellow. 36. 2532. Pastures, Scotland and Ireland. Per. 8.

Ord. 3. *Polygamia-frustranea*.

CENTAUREA. Knapweed.

1. *C. Jacea*, brown radiated. 24. 1678. Pastures, Suffex and Ireland. Per. 8, 9.
2. *C. nigra*, black leffer. 4. 278. Pastures, every where. Per. 6—8.
3. *C. Cyanus*, blue-bottle. 4. 277. Corn-fields, common. Ann. 7, 8.
4. *C. Scabiosa*, greater. 1. 56. Borders of fields. Per. 7, 8.
5. *C. Isuardi*, Jersey. 32. 2256. Pastures, Jersey. Per. 7, 8.
6. *C. Calcitrapa*, red star-thistle. 2. 125. Gravelly sandy ground. Ann. 7, 8.
7. *C. foliitalis*, yellow star-thistle. 4. 243. Fields, rare. Ann. 7, 8.

Class 20. GYNANDRIA.

Ord. 1. *Monandria*.

The natural family of the *Orchidee*, of which this order entirely consists, has lately received some fresh corrections from the able pen of Mr. R. Brown, given by Mr. Aiton in his new edition of the Hortus Kewensis, v. 5, class *Gynandria*. By these we have profited in the following arrangement, where we have adopted several of Mr. Brown's new genera; only deriving their distinctions from characters somewhat different from his. It is a strong proof of the validity of such genera, that they will stand this test. We exclude the marks taken from the absence, presence, or number, of the minute pouches whence the masses of pollen originate; not so much on account of the difficulty of having recourse to those parts in practice, but because the distinctions founded thereon do not appear to lead to the knowledge of natural genera. On the contrary, they rather shew the danger of taking any technical character as an infallible guide throughout. We have therefore not adopted the *Gymnadenia*, nor the *Habenaria* of this ingenious writer, because they seem to us naturally to belong to *Orchis*. Nevertheless, we readily submit our opinion to the correction of those who, on mature enquiry, may think otherwise. What is to become of Willdenow's *HABENARIA*, see that article, must be decided by the future study of exotic *Orchidee*, scarcely known sufficiently at present, to any European botanist, to enable him to form an opinion. See

ORCHIDEE, ORCHIS, OPHRYS, NEOTTIA, EPIPACTIS and MALAXIS.

The *Orchidee* are disposed in three very natural sections, which give the leading distinctions of the genera. 1st. Anther united to, or rather a continuation of, the column; terminal, in a manner, though sometimes surmounted by a point. 2d. Anther parallel to the stigma, and opposite to that part. 3d. Anther a terminal vertical moveable lid, either permanent or deciduous. Mr. Brown subdivides this third section, according to the anther being permanent or not, which seems to us unnecessary.

Section 1.

ORCHIS. Orchis.

Ess. Ch. Nectary with a posterior spur.

1. *O. bifolia*, butterfly. 1. 22. Woods, especially on chalk. Per. 6.

Bulbs undivided. Lip of the nectary lanceolate, entire; spur very long. Lateral calyx-leaves spreading, deflexed. This is referred to *Habenaria* by Mr. Brown, because the masses of pollen originate from two distant glands, which are naked, or destitute of a pouch at the base. The flowers are snow-white, with some touches of green, and smell powerfully, in an evening only, like a very sweet honeysuckle.

2. *O. pyramidalis*, pyramidal. 2. 110. Chalky pastures. Per. 7.

Bulbs undivided. Lip of the nectary in three equal entire segments, with two prominences above; spur elongated, thread-shaped. This and the six following, having the gland, or glands, of their masses of pollen enclosed in a single pouch, belong to the true genus of *Orchis*. *Br.*

The flowers of *O. pyramidalis* are crimson, fragrant, composing a short, dense, pyramidal spike.

3. *O. Morio*, meadow. 29. 2059. Moist pastures. Per. 5, 6.

Bulbs undivided. Lip of the nectary four-cleft, crenate; spur obtuse, ascending. Calyx many-ribbed.

Leaves without spots. Flowers purple or crimson. The three calyx-leaves cohere together, in the form of a hood, and are ribbed with green.

4. *O. mascula*, early purple. 9. 631. Meadows and groves. Per. 4, 5.

Bulbs undivided. Lip of the nectary four-cleft, crenate; spur obtuse. Lateral calyx-leaves reflexed upward.

The leaves are spotted with black. Flowers purple, scentless. Calyx-leaves with only three ribs, of their own colour. The stalk, bractees, and germen are purple.

5. *O. ustulata*, dwarf. 1. 18. Chalky hills. Per. 6.

Bulbs undivided. Lip of the nectary four-cleft, rough, with prominent points; spur obtuse, one-third the length of the germen.

Three inches high. Calyx almost black. Lip purple, with entire lobes. Flowers small.

6. *O. militaris*, narrow-lipped military. 27. 1873. Chalk hills. Per. 5.

Bulbs undivided. Lip of the nectary five-cleft, rough; segments linear. Calyx and petals taper-pointed, confluent.

A foot high. Leaves light green, unspotted. Flowers rose-coloured, their calyx paler, or whitish. This whole plant, like the following, while drying, exhales a powerful scent of melilot, woodruff, or new hay.

7. *O. fusca*, broad-lipped military. 1. 16. (*O. militaris*). Chalk hills. Per. 5.

PLANTS.

Bulbs undivided. Lip of the nectary five-cleft, rough; segments dilated. Calyx-leaves confluent. Petals linear.

Larger. *Calyx* dark brown externally. *Petals* and *nectary* pink or purple.

8. *O. hircina*, lizard. 1. 34. (*Satyrium hircinum*).
Thickets on chalk hills, very rare. Per. 7.

Bulbs undivided. Lip of the nectary three-cleft, downy; middle segment extremely long, linear, twisted, emarginate.

Largest and scarcest. British plant of this tribe, often a yard high, with from twenty to sixty flowers, whose smell is fetid, and goat-like. *Spur* shortish, green, like the *calyx* and *anther*. *Lip* two inches long, purplish-lead-coloured, with a white speckled downy disk.

9. *O. albida*, white mountain. 8. 505. (*Satyr. albidum*).
Hills. Per. 6.

Bulbs clustered, in three pairs. Lip of the nectary in three deep acute segments; spur one-third the length of the germen.

A foot high, slender. *Flowers* small, numerous, in a dense spike, white, with a green lip, nearly inodorous.— This and the next are made *Habenaria* by Mr. Brown.

10. *O. viridis*, green frog. 2. 94. (*Satyr. viride*).
Meadows. Per. 6, 7.

Bulbs clustered. Lip of the nectary linear, with three terminal teeth; the middle one smallest; spur very short, emarginate.

Five inches high. *Flowers* green, shorter than their *bracteas*. *Lip* brownish.

11. *O. latifolia*, marsh. 33. 2308. Wet meadows.
Per. 5, 6.

Bulbs clustered. Lip of the nectary crenate, obscurely three-cleft; spur conical. *Bracteas* longer than the flowers.

Stem hollow. *Leaves* unspotted. *Flowers* crimson, more or less deeply coloured.

12. *O. maculata*, spotted palmate. 9. 632. Pastures and groves. Per. 6, 7.

Bulbs palmate, spreading. Lip of the nectary crenate, three-lobed; spur cylindrical, shorter than the germen.

More slender. *Stem* solid. *Leaves* spotted. *Flowers* white, stained and dotted with violet.

13. *O. conopsea*, aromatic. 1. 10. Meadows and pastures. Per. 6.

Bulbs palmate. Lip of the nectary in three entire segments; spur bristle-shaped, twice as long as the germen.

Leaves narrow, unspotted. *Flowers* rather small, crimson, with a rich spicy odour.

This species alone constitutes Mr. Brown's genus of *Gymnadenia*, so called from *γυμνος*, naked, and *αδμη*, a gland, because the glands supporting the masses of pollen are naked, or destitute of a pouch, and stand close together. In this last character alone the genus is made to differ from *Habenaria*, whose naked glands are more or less distant from each other. It seems to us that *Habenaria nigra*, this *Gymnadenia*, and *Orchis pyramidalis*, are so nearly akin, that no assumed character ought to separate them, and that they all truly belong to the genus *Orchis*.

ACERAS. Man-Orchis.

Brown in Ait. Hort. Kew. v. 5. 191.

Eff. Ch. Calyx converging. Nectary plane, without a spur.— This genus of Mr. Brown's, whose name expresses the want of a spur, is well distinguished by that character from *Orchis*, with which it agrees in having one common pouch for the glands of the pollen. By this last mark

Mr. Brown distinguishes it, on the other hand, from the true *Ophrys*, of which we shall presently speak. We readily admit the genus, as a most natural one, only preferring the more easy characters taken from the shape of the lip, and posture of the calyx.

1. *A. anthropophora*, green. 1. 29. (*Ophrys anthropophora*). Chalk. Per. 6.

Lip of the nectary longer than the germen. *Br.*

The bulbs are globose. *Leaves* unspotted. *Spike* rather long, of numerous scentless flowers, whose closed *calyx* is green, mostly bordered with brown. *Lip* long, dependent, yellow, without spots; its segments four, shaped like those of the *Orchis militaris*, but generally without the small intermediate tooth.

HERMINIUM. Musk-Orchis.

Brown in Ait. Hort. Kew. v. 5. 191.

Eff. Ch. Calyx spreading. Petals three-lobed, shaped like the nectary, which has no spur.

This genus, and its name, are revived from the early works of Linnæus. The application of the latter, derived, as it seems, from *ἴσχυα* or *ἴσχυς*, a basis, or foundation, is not evident to us. The glands of the pollen are naked and distinct, so that it differs from *Habenaria* of Mr. Brown, as his *Aceras* does from *Orchis*, in the want of a spur. We most readily adopt the genus, only preferring, instead of a character derived from the glands, the striking one of the three-lobed petals, and their uniformity with the lip, the very same uniformity which characterises the West Indian orchideous genus of *Stelis*.

1. *H. monorchis*, small. 1. 71. (*Ophrys monorchis*).
Chalk hills. Per. 6.

Leaves radical, two, lanceolate. *Br.*

Three inches high. *Bulbs* round, one of them remote. *Leaves* light green. *Flowers* small, pale yellow, musky.

OPHRYS. Insect-Orchis.

Eff. Ch. Calyx spreading. Nectary convex, without a spur.

See the article OPHRYS, where we have given Mr. Brown's characters of this most natural genus. We wish to strengthen, not to invalidate them, by those which, in conformity to our plan, we have taken from the position of the calyx, and shape of the lip. See ACERAS just mentioned.

1. *O. muscifera*, fly. 1. 64. Chalky pastures, sparingly.
Per. 6.

Lip of the nectary four-lobed, elongated, somewhat downy; its disk polished. Column obtuse.

Bulbs ovate. *Stem* a foot high. *Leaves* unspotted. *Spike* lax. *Calyx* green. *Petals* linear, of a dull deep purple. *Lip* of the same colour, with a blueish, shining, broad, transverse stripe in the middle. The column has no terminal point.

2. *O. apifera*, bee. 6. 383. Chalky pastures. Per. 7.

Lip of the nectary five-cleft, inflated; its small terminal segment awl-shaped, recurved. Column with a hooked point.

Rather larger, with broader leaves. *Flowers* much larger. *Calyx* pale purple, with green ribs. *Petals* oblong, green, fringed with white. *Lip* resembling the body of a bee, very prominent and convex, hairy, elegantly variegated with brown and yellow; its margin bent backward, the little terminal point only being recurved forward.

3. *O. aranifera*, spider. 1. 65. Chalk-pits. Per. 4.

Lip

PLANTS.

Lip of the nectary villous, three-lobed, emarginate, pointed, deflexed. Column acute.

Of more humble growth than the last, with a green calyx, and yellowish-green petals. The lip is like the body of a spider, brown, with two principal longitudinal paler stripes, the margin pale, and bent backward, destitute of the pointed appendage seen in the *apifera*.

The *O. arachnoides*, Andr. Repof. t. 470, a native of Italy and Switzerland, not yet observed in Britain, is a very distinct species from all these. Haller has figured it in his *Historia*, t. 24, by the name of *Orchis fuciflora*; but his account and synonyms are much confused. Andrews confounds it with our *aranifera*, which is Curtis's *fucifera*, not *fuciflora*. Its character consists in the smallness of the reddish petals, which are not one-third the size of the white calyx-leaves; and especially in the margin of the very broad lip being dilated, and, as well as the pointed appendage, reflexed. This species is omitted in *Hort. Kew.* We have received it long ago from the garden of John Walker, esq. of Arno's grove, Southend.

Section 2.

NEOTTIA. Lady's Traces.

Eff. Ch. Calyx converging, embracing with its base the nectary, which has no spur. Petals converging. Column without a border. See NEOTTIA.

1. *N. spiralis*, spiral. 8. 541. (*Ophrys spiralis*.) Pastures. Per. 8, 9.
2. *N. repens*, creeping. 5. 289. (*Satyrion repens*.) Alpine woods. Per. 7.

This last is made a distinct genus by Mr. Brown, on account of a pouch under the lip; and named *Goodyera*, after the venerable and accurate contributor to the second edition of Gerarde's herbal. We lament that we are not sufficiently satisfied of its difference from *Neottia*; to which it is in habit too strictly allied, in our opinion, to be separated by the character above-mentioned.

Our *N. pubescens*, n. 17, is another species of Mr. Brown's *Goodyera*.

LISTERA. Tway-blade.

Brown in Ait. Hort. Kew. v. 5. 201.

Eff. Ch. Calyx spreading. Nectary without a spur, not embraced by the calyx. Petals spreading. Column without a border.

A very distinct genus, separated from the *Ophrys* of Linnaeus, and from the *Epipactis* of Swartz and his followers. (See EPIPACTIS, n. 10 and 11.) This genus is named in memory of Dr. Martin Lister, the celebrated conchologist, whose papers in the Philosophical Transactions, relating to the vascular system of plants, and the seeds of mushrooms, entitle him to botanical commemoration.

1. *L. ovata*, common. 22. 1548. (*Ophrys ovata*.) Woods and thickets. Per. 6.
2. *L. cordata*, heart-leaved. 5. 358. (*Ophrys cordata*.) Mountain heaths. Per. 7.

Section 3.

EPIPACTIS. Helleborine.

Eff. Ch. Anther permanent. Nectary tumid underneath, contracted in the middle. See EPIPACTIS.

1. *E. latifolia*, broad-leaved. 4. 269. (*Serapias latifolia*.) Mountainous woods. Per. 7, 8.
2. *E. palustris*, marsh. 4. 270. (*Serap. palustris*.) Boggy meadows. Per. 7, 8.

3. *E. grandiflora*, white. 4. 271. (*Serap. grandifl.*) Chalky woods. Per. 6.
4. *E. ensifolia*, narrow-leaved. 7. 494. (*Serap. ensif.*) Mountain woods. Per. 6.
5. *E. rubra*, purple. 7. 437. (*Serap. rubra*.) Mountain woods, rare. Per. 6.
6. *E. Nidus avis*, bird's nest. 1. 48. (*Ophrys Nidus avis*.) Chalky woods. Per. 6.

MALAXIS. Tender Tway-blade.

Eff. Ch. Anther deciduous. Nectary undivided, sessile, flat underneath. Petals spreading. See MALAXIS.

It seems best not to make the reversed position of the flower, an essential part of the generic character.

1. *M. paludosa*, marsh. 1. 72. Turfy bogs. Per. 7.
2. *M. Loefelii*, lily-leaved. 1. 47. (*Ophrys Loefelii*.) Sandy bogs. Per. 7.

CORALLORRHIZA. Coral-root.

Eff. Ch. Anther deciduous. Nectary elongated underneath. Petals spreading. Column unconnected.

1. *C. innata*, spur-lefs. 22. 1547. (*Ophrys corallorr.*) Boggy woods. Per. 7.

Spur of the nectary short, combined with the germen. Root very much branched.

This interesting and rare little plant has hitherto been found in Scotland only, of the British dominions. Roots sent in moss from Edinburgh, by Mr. E. J. Maughan, blossomed in our garden. These are of a fleshy substance, much branched and divaricated, spreading horizontally; they still exhale, after having been seven years dried, a very sweet smell, like Vanilla. The slender stem, a span high, is invested with a few sheaths, but destitute of leaves, and bears a loose spike of a few small yellowish flowers. Mr. Brown, who has finally established this genus, detected the minute and concealed spur. We have a number of exotic species, especially from the East Indies, which seem to belong to Corallorrhiza. Their fleshy tuberous roots, and leafless scaly stems, are peculiar; and, like other species from North America, some of these plants have an evident spur, others an obsolete or concealed one.

Ord. 2. Diandria.

CYPRIPEDIUM. Ladies'-slipper.

Eff. Ch. Calyx spreading. Petals spreading. Nectary inflated. Column with a posterior appendage.

1. *C. Calceolus*, common. 1. 1. Northern woods, rare. Per. 6.

Stem leafy. Appendage of the column elliptical, obtuse, channelled. Petals flat.

The figure in Engl. Bot. unfortunately represents the appendage as if angular and acute; inasmuch that it has been supposed to have been drawn from an American species, known by that character; but this supposition is refuted by a comparison of the plants. (See CYPRIPEDIUM.) The calyx, as we deem it, of this genus is considered by authors as composed of three leaves, like all the rest of the *Orchidex*; though the two lowermost are, for the most part, nearly united into one.

Ord. 3. Hexandria.

ARISTOLOCHIA. Birthwort.

1. *A. Clematidis*, common. 6. 398. Thickets and rubbish. Per. 7, 8.

PLANTS.

Class 21. MONOECIA.

Ord. 1. Monandria.

ZANNICHELLIA. Horned Pondweed.

1. *Z. palustris*, common. 26. 1844. Ditches and pools. Ann. 7.

Ord. 2. Triandria.

TYPHA. Reed-mace.

1. *T. latifolia*, great. 21. 1455. Pools and ditches. Per. 7.
 2. *T. angustifolia*, lesser. 21. 1456. Pools, rare. Per. 6, 7.
 3. *T. minor*, dwarf. 21. 1457. Marshes, rare. Per. 7.

SPARGANIUM. Bur-reed.

1. *S. ramosum*, branched. 11. 744. Rivers and ditches. Per. 7, 8.
 2. *S. simplex*, unbranched. 11. 745. Waters, on gravel. Per. 7, 8.
 3. *S. natans*, floating. 4. 273. Rivers and pools. Per. 7.

CAREX. Sedge.

1. *C. dioica*, common separate-headed. 8. 543. Bogs. Per. 5, 6.
 2. *C. Davalliana*, prickly separate-headed. 30. 2123. Marshes. Per. 5, 6.
 3. *C. pulicaris*, flea. 15. 1051. Marshes. Per. 6.
 4. *C. pauciflora*, few-flowered. 29. 2041. Alpine bogs. Per. 6.
 5. *C. stellulata*, little prickly. 12. 806. Marshes. Per. 5, 6.
 6. *C. curta*, white. 20. 1386. Watery places, rare. Per. 6.
 7. *C. elongata*, elongated. 27. 1920. Marshes, Yorkshire. Per. 6.
 8. *C. ovalis*, oval-spiked. 5. 306. Marshes. Per. 6.
 9. *C. remota*, remote. 12. 832. Moist groves. Per. 5, 6.
 10. *C. axillaris*, axillary clustered. 14. 993. Bogs, rare. Per. 5, 6.
 11. *C. incurva*, curved. 13. 927. Sandy mouths of rivers, rare. Per. 7, 8.
 12. *C. arenaria*, flea. 13. 928. Sandy coast, abundantly. Per. 6.
 13. *C. intermedia*, soft brown. 29. 2042. Marshes. Per. 5, 6.
 14. *C. divisa*, bracteated marsh. 16. 1096. Salt marshes. Per. 5, 6.
 15. *C. muricata*, greater prickly. 16. 1097. Moist meadows. Per. 5, 6.
 16. *C. divulsa*, grey. 9. 629. Moist shady places. Per. 5.
 17. *C. vulpina*, great spiked. 5. 307. Marshes. Per. 5.
 18. *C. teretiuscula*, lesser paniced. 15. 1065. Marshes. Per. 5.
 19. *C. paniculata*, great paniced. 15. 1064. Bogs. Per. 6.
 20. *C. digitata*, fingered. 9. 615. Woods, on limestone. Per. 5.
 21. *C. clandestina*, dwarf silvery. 30. 2124. Sunny rocks. Per. 5.
 22. *C. pendula*, great pendulous. 33. 2315. Moist hedges. Per. 5, 6.

23. *C. strigosa*, loose pendulous. 14. 994. Groves. Per. 4, 5.
 24. *C. sylvatica*, pendulous wood. 14. 995. Woods, frequent. Per. 5, 6.
 25. *C. depauperata*, starved wood. 16. 1098. Woods, rare. Per. 5, 6.
 26. *C. Micheliana*, loose-spiked rock. 32. 2293. Alpine rocks. Per. 8.

Sheaths not half the length of the flower-stalk. Female spikes three, distant, erect, lax and slender. Fruit ovate, triangular, bluntly cloven, twice the length of the obtuse scale.

Willdenow, in Sp. Pl. v. 4. 276, gives a citation of Schkuhr's *Carices*, fig. 198, and adds that this is Hoppe's *C. alpina*. It has however nothing to do with *alpina* of Wahlenberg; see CAREX, n. 97.

27. *C. capillaris*, capillary. 29. 2069. Highland mountains. Per. 7, 8.

28. *C. variflora*, loose alpine. 35. 2516. Lofty Highland mountains. Per. 7.

Sheaths extremely short. Female spikes nearly linear, pendulous; their scales loosely imbricated. Fruit obovate, with three blunt angles and depressed sides. Root creeping.

Wahlenberg makes this a variety of *limosa*, n. 30, with which it agrees in the creeping root, short sheaths, and drooping female spikes; but differs in its obovate, triangular, (not broad and compressed), fruit; much smaller size; and lax blacker scales.

29. *C. Pseudo-cyperus*, bastard-cyperus. 4. 242. Marshes. Per. 6.

30. *C. limosa*, green and gold. 29. 2043. Spongy boggy pools. Per. 6.

31. *C. ustulata*, scorched alpine. 34. 2404. Alpine rivulets. Per. 7. See CAREX, n. 127.

32. *C. atrata*, black. 29. 2044. Alpine meadows. Per. 6, 7.

33. *C. pulla*, ruffet. 29. 2045. Alpine pastures. Per. 7.

34. *C. pallens*, pale. 31. 2185. Meadows and groves. Per. 5, 6.

35. *C. flava*, yellow. 18. 1294. Marshes. Per. 5, 6.

36. *C. fulva*, tawny. 18. 1295. Marshes. Per. 6, 7.

37. *C. Oederi*, Oederian. 25. 1773. Moist meadows. Per. 7.

38. *C. extensa*, long-bracteated. 12. 833. Sea-coast. Per. 6.

39. *C. distans*, loose. 18. 1234. Marshes. Per. 6.

40. *C. binervis*, green-ribbed. 18. 1235. Dry heaths. Per. 6.

41. *C. praecox*, vernal. 16. 1099. Open pastures, common. Per. 4.

42. *C. pilulifera*, round-headed. 13. 885. Pastures and heaths. Per. 4, 5.

43. *C. tomentosa*, downy-fruited. 29. 2046. Meadows, rare. Per. 6.

44. *C. rigida*, rigid. 29. 2047. Lofty mountains. Per. 6, 7.

45. *C. panicea*, pink-leaved. 21. 1505. Moist meadows. Per. 5, 6.

46. *C. recurva*, glaucous heath. 21. 1506. Pastures and heaths. Per. 5, 6.

C. Micheliana, Fl. Brit. 1004. E. B. 32. 2236, is now found to be only a variety of *recurva*, with smooth fruit, and several male spikes.

47. *C. caespitosa*, tufted bog. 21. 1507. Marshes. Per. 5.

48. *C. stricta*, glaucous straight-leaved. 13. 914. Marshes. Per. 4.

PLANTS.

49. *C. acuta*, slender-spiked. 9. 580. Watery places. Per. 5.
 50. *C. paludosa*, lesser common. 12. 807. Watery places. Per. 5.
 51. *C. riparia*, great common. 9. 579. Watery places. Per. 4, 5.
 52. *C. levigata*, smooth-stalked beaked. 20. 1387. Bogs. Per. 5.
 53. *C. vesicaria*, short-spiked bladder. 11. 779. Marshes. Per. 5.
 54. *C. ampullacea*, slender-beaked bladder. 11. 780. Bogs. Per. 5.
 55. *C. hirta*, hairy. 10. 685. Boggy meadows. Per. 5, 6.
 56. *C. filiformis*, slender-leaved. 13. 904. Bogs, rare. Per. 6.

KOBRESIA. Kobresia.

1. *K. caricina*, sedgey. 20. 1410. Moist mountains. Per. 8.

ERIOCAULON. Pipewort.

1. *E. septangulare*, jointed. 11. 733. Lakes, Scotland and Ireland. Per. 9.

Ord. 3. Tetrandria.

LITTORELLA. Shore-weed.

1. *L. lacustris*, plantain. 7. 468. Sandy puddles. Per. 6.

BETULA. Birch.

1. *B. alba*, common. 31. 2198. Sandy or mountain woods. Tree. 4, 5.
 2. *B. nana*, dwarf. 33. 2326. Boggy mountain heaths. Shrub. 5.
 3. *B. Alnus*, alder. 21. 1508. Watery meadows. Tree. 3.

BUXUS. Box.

1. *B. sempervirens*, common. 19. 1341. Chalky hills. Shrub. 4.

URTICA. Nettle.

1. *U. pilulifera*, Roman. 3. 148. Rubbish on the coast. Ann. 6, 7.
 2. *U. urens*, small. 18. 1236. Cultivated ground. Ann. 6—10.
 3. *U. dioica*, great. 25. 1750. Waste ground. Per. 7, 8.

Ord. 4. Pentandria.

XANTHIUM. Bur-weed.

1. *X. strumarium*, small burdock. 36. 2544. Dunghills, rare. Ann. 8, 9.

AMARANTHUS. Amaranth.

1. *A. Blitum*, wild. 31. 2212. Dunghills, rare. Ann. 8.

BRYONIA. Bryony.

1. *B. dioica*, red-berried. 7. 439. Hedges. Per. 5—9.

Ord. 5. Polyandria.

CERATOPHYLLUM. Hornwort.

1. *C. demersum*, common. 14. 947. Ditches, frequent. Per. 8, 9.
 2. *C. submersum*, unarmed. 10. 679. Ditches, rare. Per. 9.

MYRIOPHYLLUM. Water-millfoil.

1. *M. spicatum*, spiked. 2. 83. Ditches and ponds. Per. 7, 8.
 2. *M. verticillatum*, whorled. 4. 218. Ponds, rare. Per. 7.

SAGITTARIA. Arrow-head.

1. *S. sagittifolia*, common. 2. 84. Rivers and ditches. Per. 7, 8.

ARUM. Cuckow-pint.

1. *A. maculatum*, spotted. 19. 1298. Thickets and woods. Per. 5.

POTERIUM. Garden-Burnet.

1. *P. Sanguisorba*, common. 12. 860. Chalky hills. Per. 7.

QUERCUS. Oak.

1. *Q. Robur*, common British. 19. 1342. Woods and hedges. Tree. 4.
 2. *Q. sessiliflora*, sessile-fruited. 26. 1845. Woods. Tree. 4, 5.

FAGUS. Beech.

1. *F. Castanea*, sweet chestnut. 13. 886. Woods. Tree. 5.
 2. *F. sylvatica*, common. 26. 1846. Chalky hills. Tree. 4, 5.

CARPINUS. Horn-beam.

1. *C. Betulus*, common. 29. 2032. Woods, on clay. Tree. 5.

CORYLUS. Nut.

1. *C. Avellana*, hazel. 11. 723. Woods and hedges. Small tree. 3, 4.

Ord. 6. Monadelphica.

PINUS. Fir.

1. *P. sylvestris*, common Scotch. 35. 2460. Scottish hills. Tree. 5.

Class 22. DIOECIA.

Ord. 1. Diandria.

SALIX. Willow.

1. *S. purpurea*, bitter purple. 20. 1388. Marshes, rare. Shrub. 3.
 2. *S. Helix*, rose. 19. 1343. Marshes. Small tree. 3, 4.
 3. *S. Lambertiana*, Boyton. 19. 1359. Banks of rivers. Small tree. 3, 4.
 4. *S. Forbiana*, basket osier. 19. 1344. Osier holts. Shrub. 4.
 5. *S. rubra*, green osier. 16. 1145. Osier holts. Small tree. 4, 5.
 6. *S. Croceana*, broad-leaved monadelphous. 16. 1146. Marshes. Small tree. 4, 5.
 7. *S. triandra*, long-leaved triandrous. 20. 1435. Meadows. Tree. 5 and 8.
 8. *S. lanceolata*, sharp-leaved triandrous. 20. 1436. Meadows. Tree. 4, 5.
 9. *S. amygdalina*, almond-leaved. 27. 1936. Marshes. Tree. 4, 5.

PLANTS.

10. *S. decipiens*, varnished. 27. 1936. Woods and hedges. Tree. 5.
11. *S. Ruffelliana*, Bedford. 26. 1808. Woods and meadows. Tall tree. 4, 5.
12. *S. fragilis*, crack. 26. 1807. Meadows and marshes. Tree. 4, 5.
13. *S. pentandra*, bay-leaved. 26. 1805. Banks of rivers. Tree. 5, 6.
14. *S. nigricans*, dark broad-leaved. 17. 1213. Meadows. Small tree. 4.
15. *S. bicolor*, shining dark-green. 26. 1806. Woods. Shrub. 4, 5.
- †16. *S. petiolaris*, dark long-leaved. 16. 1147. Marshes. Shrub. 4.
17. *S. phyllifolia*, tea-leaved. 28. 1958. Highlands of Scotland. Shrub. 5.
- S. radicans*, Fl. Brit. 1053, proves to be the same species.
18. *S. Arbuscula*, little tree. 19. 1366. Mountains of Scotland. Shrub. 4.
19. *S. vitellina*, yellow. 20. 1389. Marshy meadows. Tree. 5.
20. *S. tenuifolia*, thin-leaved. 31. 2186. Stony hills. Shrub. 5, 6.
21. *S. malifolia*, apple-leaved. 23. 1617. Hills? Shrub. 5.
22. *S. myrsinites*, green whortle-leaved. 19. 1360. Highlands. Shrub. 5, 6.
23. *S. prunifolia*, plum-leaved. 19. 1361. Highlands. Shrub. 4, 5.
24. *S. venulosa*, veiny-leaved. 19. 1362. Highlands. Shrub. 4, 5.
25. *S. vacciniifolia*, bilberry-leaved. 33. 2341. Scotland. Shrub. 4.
26. *S. carinata*, folded-leaved. 19. 1363. Highlands. Shrub. 4.
27. *S. Dicksoniana*, broad-leaved mountain. 20. 1390. Highlands. Shrub. 4.
- S. myrtilloides*, Fl. Brit. 1056, but not of Linnæus.
28. *S. herbacea*, leaf. 27. 1907. Micaceous mountains. Small shrub. 6.
29. *S. reticulata*, wrinkled. 27. 1908. Highlands. Small shrub. 6.
30. *S. arenaria*, downy mountain. 26. 1809. Highlands. Shrub. 5.
31. *S. glauca*, glaucous mountain. 26. 1810. Highlands. Shrub. 5.
32. *S. Stuartiana*, shaggy mountain. 36. 2586. Highlands. Shrub. 7.
33. *S. argentea*, silky fand. 19. 1364. Sandy sea-coast. Shrub. 5.
34. *S. prostrata*, prostrate dwarf. 28. 1959. Moift hills. Small shrub. 5, 6.
35. *S. fufca*, brownish dwarf. 28. 1960. Mountainous heaths. Small shrub. 5.
36. *S. parvifolia*, fmall-leaved dwarf. 28. 1961. Moift meadows. Shrub. 5.
37. *S. adfcendens*, afcending dwarf. 28. 1962. Moift heaths. Shrub. 5.
38. *S. repens*, creeping dwarf. 3. 183. Sandy moift heaths. Small shrub. 5.
39. *S. rofmarinifolia*, rofemary-leaved. 19. 1365. Moift fand. Shrub. 4, 5.
40. *S. cinerea*, grey. 27. 1897. Woods. Small tree. 5.
41. *S. aurita*, round-eared fallow. 21. 1487. Woods. Shrub. 4, 5.
42. *S. aquatica*, common water fallow. 20. 1437. Wet thickets. Small tree. 4.
43. *S. oleifolia*, olive-leaved fallow. 20. 1402. Woods and hedges. Tree. 3.
44. *S. rupeftris*, filky rock. 33. 2342. Highland rocks. Small shrub. 4.
45. *S. Anderfoniana*, green mountain fallow. 33. 2343. Scotland. Shrub. 5.
46. *S. Forfteriana*, glaucous mountain fallow. 33. 2344. Scotland. Small tree. 5.
47. *S. cotinifolia*, quince-leaved. 20. 1403. Woods. Shrub. 4.
48. *S. hirta*, hairy branched. 20. 1404. Woods. Small tree. 4, 5.
49. *S. fphacelata*, withered-pointed. 33. 2333. Scotland. Tree. 4, 5.
50. *S. caprea*, great round-leaved fallow. 21. 1488. Dry woods. Tree. 4.
51. *S. acuminata*, long-leaved fallow. 20. 1434. Moift woods. Tree. 4.
52. *S. flipularis*, auricled ofier. 17. 1214. Ofier holts. Tree. 3.
53. *S. molliffima*, velvet ofier. 21. 1509. Ofier holts. Small tree. 4.
54. *S. viminalis*, common ofier. 27. 1898. Ofier holts, &c. Tree. 4, 5.
55. *S. alba*, common white. 34. 2430. Woods and meadows. Tree. 4, 5.
56. *S. cærulea*, blue. 34. 2431. Moift meadows. Large tree. 5.

Ord. 2. Triandria.

EMPETRUM. Crake-berry.

1. *E. nigrum*, black. 8. 526. Mountain moors. Small shrub. 5.

RUSCUS. Butcher's-broom.

1. *R. aculeatus*, common. 8. 560. Woods and thickets. Per. 3, 4.

Ord. 3. Tetrandria.

VISCUM. Miffeltoe.

1. *V. album*, white. 21. 1470. On trees. Small shrub. 5.

HIPPOPHÆE. Sallow-thorn.

1. *H. rhamnoides*, fea. 6. 425. Sandy cliffs. Small tree. 5.

MYRICA. Gale.

1. *M. Gale*, fweet. 8. 562. Spongy bogs. Shrub. 5.

Ord. 4. Pentandria.

HUMULUS. Hop.

1. *H. Lupulus*, common. 6. 427. Thickets and hedges. Per. 7.

Ord. 5. Hexandria.

TAMUS. Black-bryony.

1. *T. communis*, common. 2. 91. Woods and hedges. Per. 6.

PLANTS.

Ord. 6. *Oëandria*.

POPULUS. Poplar.

1. *P. alba*, white. 23. 1618. Moist woods, or hills. Tree. 3.
2. *P. canescens*, grey. 23. 1619. Watery meadows. Tree. 3.
3. *P. tremula*, aspen. 27. 1909. Boggy woods. Tree. 3, 4.
4. *P. nigra*, black. 27. 1910. Watery weadows. Tree. 3.

RHODIOLA. Rose-root.

1. *R. rosea*, mountain. 8. 508. Alpine rocks. Per. 5, 6.

Ord. 7. *Enneandria*.

MERCURIALIS. Mercury.

1. *M. perennis*, perennial. 26. 1872. Groves and thickets. Per. 4, 5.
2. *M. annua*, annual. 8. 559. Rubbish. Ann. 7—9.

HYDROCHARIS. Frog-bit.

1. *H. Morfus ranae*, common. 12. 808. Ditches. Per. 7.

Ord. 8. *Monadelphia*.

JUNIPERUS. Juniper.

1. *J. communis*, common. 16. 1100. Chalky downs. Shrub. 5.

TAXUS. Yew.

1. *T. baccata*, common. 11. 746. Woods and rocks. Tree. 3, 4.

Class 23. POLYGAMIA.

Ord. 1. *Monocia*.

ATRIPLEX. Orache.

1. *A. portulacoides*, shrubby. 4. 261. Muddy sea-coast. Small shrub. 7, 8.
2. *A. laciniata*, frosted sea. 3. 165. Sandy coast. Ann. 7.
3. *A. patula*, spreading halberd-leaved. 13. 936. Rubbish. Ann. 6—8.
4. *A. angustifolia*, spreading narrow-leaved. 25. 1774. Rubbish. Ann. 6—8.
5. *A. erecta*, upright spear-leaved. 31. 2223. Fields, rare. Ann. 8.
6. *A. littoralis*, grass-leaved sea. 10. 708. Muddy coast. Ann. 8, 9.
7. *A. pedunculata*, stalked sea. 4. 232. Muddy coast, rare. Ann. 8, 9.

Pallas in his *Travels*, English edition v. 1. 291, calls this last species *Ceratocarpus salinus*.

Class 24. CRYPTOGAMIA.

Ord. 1. *Filices*.

EQUISETUM. Horfe-tail.

Seven species, chiefly found in moist or watery places. Perennial. 4—8.

BOTRYCHIUM. Moon-wort.

Swartz Syn. Fil. 8.

Eff. Ch. Capsules without a ring, globose, even, sessile on a compound flattened stalk.

1. *B. Lunaria*, common. 5. 318. (*Osmunda Lunaria*). Pastures. Per. 6.

Fronde pinnate, flowering from its base; leaflets crescent-shaped, crenate.

A span high, smooth, pale green, simply pinnate, with about six pair of leaflets, and one branched spike.

OSMUNDA. Osmund-royal.

1. *O. regalis*, common. 3. 209. Shady bogs. Per. 6, 7.

LYCOPODIUM. Club-moss.

- Six species. Heathy mountainous places. Per. 6—8.

POLYPODIUM. Polypody.

- Four species. Walls or dry hills. Per. 5—10.

ASPIDIUM. Shield-fern.

Twelve species. Rocks, heaths, bogs, or shady places. Per. 5—7.

This genus differs from *Polypodium*, only in having a membranous involucre to the dots of fructification. See POLYPODIUM.

ASPLENIUM. Spleenwort.

- Eight species. Rocks or walls. Per. 3—10.

SCOLOPENDRIUM. Hart's-tongue.

1. *S. vulgare*, common. 16. 1150. Moist shady places. Per. 7.
2. *S. Ceterach*, scaly. 18. 1244. Rocks and walls. Per. 4—10.

BLECHNUM. Blechnum.

1. *B. boreale*, northern. 17. 1159. Dry stony heaths. Per. 7.

PTERIS. Brake.

1. *P. aquilina*, common. 24. 1679. Pastures and woods. Per. 7.
2. *P. crispa*, rock. 17. 1160. Stony hills in the north. Per. 7.

ADIANTUM. Maiden-hair.

1. *A. Capillus-Veneris*, true. 22. 1564. Marine rocks, rare. Per. 5—9.

CYATHEA. Cup-fern.

- Three species. Rocks or walls. Per. 6. 7.

WOODSIA. Brittle-fern.

Brown Tr. of Linn. Soc. v. 11. 170. t. 11.

1. *W. hyperborea*, alpine. 29. 2023. (*Polypodium hyperboreum*.) Rocks. Per. 6.

TRICHOMANES. Hair-fern.

1. *T. brevifetum*, short-bristled. 20. 1417. (*Hymenophyllum alatum*.) Wet rocks in Yorkshire and Ireland, rare. Per. 5, 6.

HYMENOPHYLLUM. Filmy-fern.

1. *H. Tunbridgense*, Tunbridge. 3. 162. Moist rocks. Per. 5, 6.

PILULARIA. Pillwort.

1. *P. globulifera*, pepper-grass. 8. 521. Moist heaths. Per. 6, 7.

ISOETES.

PLANTS.

ISOETES. Quillwort.

1. *I. lacustris*, mountain. 16. 1084. Alpine lakes. Per. 5, 6.

Ord. 2. *Musci*.

SPHAGNUM. Bog-mofs.

Four species. Clear watery bogs. Per. 6.

BUXBAUMIA. Buxbaumia.

1. *B. aphylla*, naked-stalked. 23. 1596. Barren heaths, rare. Ann. 12—2.
2. *B. foliosa*, leafy. 5. 329. Shady rocks. Ann. 7.

PHASCOM. Earth-mofs.

Seventeen species. Banks, heaths and woods. Ann. 3—5.

GYMNOSTOMUM. Beardless mofs.

Twenty species. Banks, rocks, and mountains. Ann. or per. 3—8.

SPLACHNUM. Gland-mofs.

Thirteen species. Mountains or bogs, or dung. Ann. 5, 6.

ANDRÆA. Andræa.

Fl. Brit. 1178. *Hooker Tr. of Linn. Soc.* v. 10. 381. See ANDRÆA, JOHN.

Eff. Ch. Capsule oblong, of four valves, whose points adhere to the lid. Fringe none.

1. *A. rufifris*, dusky rock. 18. 1277. Moist alpine rocks. Per. 6.

Leaves lanceolate, keeled, sickle-shaped, leaning one way, without a rib.

2. *A. Rothii*, black mountain. 31. 2162. Dry rocks. Per. 6.

Leaves lanceolate, keeled, sickle-shaped, with a mid-rib, leaning one way. Sheath-scales without a rib.

3. *A. alpina*, chocolate alpine. 18. 1278. Alpine rocks. Per. 6.

Leaves ovate-oblong, concave, ribless, imbricated every way.

4. *A. nivalis*, tall slender. 33. 2334. Lofty alpine rocks. Per. 6.

Leaves loosely imbricated, lanceolate, curved towards one side, single-ribbed, as well as the sheath-scales.

This last is three inches, or more, in height, being much taller, and more branched, than any of the rest. The character of the genus was totally mistaken by Hedwig and others, the valves of the capsule being supposed the fringe, till Mr. W. J. Hooker corrected the character, as above. See FRINGE of *Mosses*.

TETRAPHIS. Four-toothed-mofs.

1. *T. pellucida*, transparent. 15. 1020. Wet shady places. Ann. 3, 4.

Capsule cylindrical. Leaves ovate, acute, single-ribbed.

2. *T. ovata*, dusky. 22. 1422. (*Grimmia Browniana*.)

Sand rocks. Ann. 3.

Capsule ovate. Radical leaves strap-shaped, obtuse, ribless.

Great diversity of opinion has existed respecting the genus of this moss, referred to *Orthotrichum* in *Fl. Brit.* 1269, and incorrectly drawn, as to the fringe, in *Engl. Bot.* A German botanist, named Funk, has shewn that part to con-

sist of four teeth only. This species must be allowed to accord very ill in habit with the first.

ENCALYPTA. Extinguisher-mofs.

Five species. Banks and rocks. Per. 3—8.

GRIMMIA. Grimmia.

Thirty-one species. Banks, rocks, and trees. Mostly per. 4—7.

From these is to be deducted *G. Forsteri*, 31. 2225, as being the same with *Mnium conoidicum*. See GRIMMIA and MNIMUM.

DICRANUM. Fork-mofs.

Forty-eight species. Woods, hills and bogs. Mostly per. 4—8.

From this genus, as it stands in *Fl. Brit.*, four species are to be deducted; *callistomum*, n. 15, as being the same with *rigidulum*, *Engl. Bot.* 20. 1439; *pulvinatum*, n. 21, removed to *Grimmia*, 24. 1728; *sciuroides*, n. 22, removed to *Pterogonium*, 27. 1903; and *viridissimum*, n. 34, removed to *Gymnostomum*, 22. 1583. Their place is supplied by four others; *Bruntoni*, 35. 2509; *Starkii*, 31. 2227; *latifolium*, 35. 2492; and *virens*, 31. 1462.

TRICHOSTOMUM. Fringe-mofs.

Eighteen species. Rocks, heaths or water. Per. 4—8. *T. cirratum*, *Fl. Brit.* n. 6, is to be expunged, as not differing from *Dicranum polyphyllum*, 17. 1217.

TORTULA. Screw-mofs.

Nineteen species. Banks, heaths and walls. Per. 3—12.

ORTHOTRICHUM. Bristle-mofs.

Eleven species. Trees, wet rocks, &c. Per. 1—4.

O. Brownianum, *Fl. Brit.* 1269, is *Tetraphis ovata*.

PTEROGONIUM. Wing-mofs.

Six species. Trees and rocks. Per. 4, 5.

We postpone remarks on this genus till it comes in its proper place. See PTEROGONIUM.

NECKERA. Neckera.

Six species. Trees and rocks. Per. 2—4.

Among them is the following very curious moss, discovered since our article NECKERA was published.

N. splachnoides. Pear-fruited Neckera. 36. 2564.

Stem branched, spreading. Leaves lanceolate, pointed, flat, spreading every way; those of the sheath fix, in two rows. Fruit-stalk granulated above. Capsule erect, contracted at the base. Veil fringed.

Found by Dr. Taylor on the Secawn mountain near Dublin.

HYPNUM. Feather-mofs.

Eighty-one species. Trees, rocks and bogs. Per. 2—10.

From the 77 species in *Fl. Brit.* are to be removed *lucens*, n. 25, which is *Hookeria lucens*; and *filamentosum*, n. 42, which has been shewn by Dr. Swartz to be the same as *dubium*, n. 74. Six are added in their stead; *pratense*, *Turn. Mufc. Hib.* 161; *filetanum*, *Engl. Bot.* 28. 2016; *Thuringicum*, *Turn. Mufc. Hib.* 181; *squarrosulum*, 24. 1709; *fallax*, 30. 2127; and *Crista-castrensis*, 30. 2108.

HOOKERIA. Hookeria.

1. *H. lucens*, shining. 27. 1902. Shady bogs. Per. 4—7.

PLANTS.

FONTINALIS. Water-moss.

Three species. Running waters. Per. 7, 8.

FUNARIA. Cord-moss.

1. *F. hygrometrica*, twisting. 5. 342. (*Bryum hygrometricum*). Sandy ground. Ann. 4, 5.
Stem none. Leaves concave, converging, entire, acute. Capfule obovate. Lid convex.
2. *F. Muhlenbergii*, hair-pointed. 21. 1497. Mountain heaths. Ann. 4, 5.
Stem short, simple. Leaves concave, finely ferrated, hair-pointed. Capfule oblique. Lid slightly conical.
3. *F. Templetoni*, long-fruited. 36. 2524. Ireland. Per. 5?
Stem elongated, somewhat branched. Leaves spreading, ovate, entire, acute. Capfule obovate, tapering at the base.

BARTRAMIA. Bartramia.

Ess. Ch. Capfule spherical, at length furrowed. Outer fringe of 16 tapering teeth; inner a plaited membrane.

The original *Bartramia* being referred to *Triumfetta*, this genus of mosses has been dedicated to the memory of Mr. John Bartram, the venerable correspondent of Linnæus, Collinson, Fothergill and other naturalists, who during his travels in North America, contributed greatly to enrich the gardens and museums of Europe. See the end of the article BRYUM. We here subjoin a more ample list of British species.

1. *B. Halleriana*, lateral. 14. 997. Mountain rivulets. Per. 6, 7.
Fruit-stalks lateral, curved, shorter than the linear-awl-shaped, single-ribbed, even leaves.
2. *B. pomiformis*, apple. 14. 998. Shady rocks and banks. Per. 4, 5.
Fruit-stalks erect, surmounting the stems. Leaves awl-shaped, single-ribbed.
3. *B. crispata*, frizzled. 22. 1526. Northumberland. Per. 4, 5.
Fruit-stalks erect, surmounting the stems. Leaves linear-awl-shaped, broad at the base, curled when dry. Capfule rather oblique. Lid obtusely conical.
4. *B. ibyphylla*, straight-leaved. 24. 1710. Wales and north of England. Per. 5.
Fruit-stalks surmounting the stems. Leaves capillary, with a very broad base, entire; very straight when dry.
5. *B. gracilis*, tall slender. 26. 1826. Highlands. Per. 7, 8.
Fruit-stalks erect, surmounting the stems. Leaves lanceolate, revolute, single-ribbed; ferrated towards the point. Stems elongated.
6. *B. fontana*, fountain. 6. 390. (*Bryum fontanum*). Boggy mountains. Per. 6, 8.
Fruit-stalks erect, much taller than the clustered, erect, thread-shaped branches. Leaves ovate, entire.
7. *B. marchica*, bog. 29. 2074. Highland water-falls. Per.
Fruit-stalks erect, taller than the stems. Leaves lanceolate, finely ferrated, imbricated in five rows. Branches clustered, slender, upright.
8. *B. arcuata*, curve-stalked. 18. 1237. Mountain bogs, rare. Per. 7.
Fruit-stalks recurved. Leaves lanceolate, furrowed, finely ferrated. Branches scattered, spreading.

MNIUM. Spring-moss.

1. *M. androgynum*, narrow-leaved. 18. 1238. Shady wet places. Per. 3, 4.

2. *M. coinodeum*, club-fruited. 18. 1239. Trees. Per.
3. *M. palustre*, greater forked. 6. 391. (*Bryum palustre*.) Bogs. Per. 5—7.

BRYUM. Thread-moss.

Thirty-four species. Heaths, bogs, mountains. Mostly per. 3—9.

A full account of the thirty-three species of Fl. Brit. is given by our excellent predecessor, the Rev. Mr. Wood; see BRYUM. From these we have only to remove the *inclians*, n. 23, which Mr. F. Eagle has discovered to be no other than *Dicranum virens*, E. B. 21. 1462.—*B. cylindricum*, n. 6, is *longicollum*, Swartz Musc. Suec. 49. t. 6. f. 13. *Webera longicolla* of Hedwig.—*B. marginatum*, n. 20, is *ferratum*, Schrad. Spicil. 71. Two species are to be added.

- B. triquetrum*, long stalked. 34. 2394. Bogs, Ireland. Per. 7.

Stem subdivided. Branches simple, erect. Leaves spreading in three rows, ovato-lanceolate, sharp-pointed, finely ferrated. Capfule slender-pear-shaped, oblique and incurved. Lid conical. The *fruitstalks* exceed all other British mosses in length, extending to three or four inches.

- B. obtusifolium*, blunt-leaved. Turn. Musc. Hib. 116. t. 11. f. 1. Ireland.

“Stem nearly simple. Leaves ovate, obtuse, concave, converging. Capfule obovate, oblique. Lid bossed.” This is one of the very few mosses of which specimens have not yet been procured for delineation in *Engl. Bot.*

POLYTRICHUM. Hair-moss.

Sixteen species. Heaths and mountains. Per. or ann. 3—8. See POLYTRICHUM hereafter.

Ord. 3. Hepatica.

JUNGERMANNIA. Jungermannia.

Above seventy species, now illustrating by Mr. W. J. Hooker, in an elegant and learned monograph. Sixty-eight are figured in *Engl. Bot.*

BLASIA. Blasia.

1. *B. pusilla*, dwarf. 19. 1328. Damp sandy places. Ann. 10, 11.

TARGIONIA. Targionia.

1. *T. hypophylla*, dotted. 4. 287. Shady banks, rare. Per. 3, 4.

SPHÆROCARPUS. Bladder-grain.

1. *P. terrestris*, reticulated. 5. 299. Turnip and clover fields. Ann. 11.

MARCHANTIA. Marchantia.

Five species. Shady places, or rocks. Per. Various seasons.

RICCIA. Riccia.

Four species. Sandy heaths, or in ponds. Ann? 8—12. *R. fruticulosa* is a *Jungermannia*, probably not distinct from *furcata*. See E. B. 35. 2514.

ANTHOCEROS. Horn Liverwort.

1. *A. punctatus*, jagged-leaved. 22. 1537. Damp sandy ground. Ann. 6.

2. A.

PLANTS.

2. *A. major*, broad-leaved. 22. 1538. With the former. Ann. 6.

A. lewis of Linnæus, who erroneously supposed it had no warts, or male flowers.

3. *A. multifidus*, fine-cut. Dill. t. 68. f. 4. Highland rocks. *Dickson*.

Ord. 4. *Algæ*.

This order begins with the natural family of LICHENES; (see that article.) Of these, 391 are figured in *Engl. Bot.*; but several still remain for further examination. An ample view of numerous species, both native and exotic, may be found under the article LICHEN; and their terminology, physiology, and generic distribution, under LICHENES.

The following, except the first genus, which is of an amphibious nature, are aquatic, or submersed, *Algæ*.

TREMELLA. Jelly-bladder.

About twenty species, found on rotten wood, in water, or on the ground, after much wet.

ULVA. Laver.

About thirty-five species. In fresh or salt water. Ann. or per. Various seasons.

FUCUS. Fucus.

About ninety species. In salt water. Ann. or per. Various seasons.

RIVULARIA. Rivularia.

Eleven species are figured in *Engl. Bot.* Fresh or salt water.

CONFERVA. Conferva.

About 180 species. Fresh or salt water, at various seasons. Above 130 are figured in *Engl. Bot.*

VAUCHERIA. Vaucheria.

Three or four, not very well defined, species, found in fresh water: See *Engl. Bot.* v. 25.

BYSSUS. Byffus.

Hudson has nineteen species of this genus, but the number is much lessened in consequence of subsequent enquiries; inasmuch that it is hard to say what really constitutes a *Byffus* at all. The fibrous kinds are generally reducible to *Conferva*, the powdery ones to *Lepraria*. Some of the latter indeed, having occasionally produced shields, prove themselves either *Lecideæ* or *Parmeliæ*. See LICHENES.

Ord. 5. *Fungi*.

Withering, who excels in this obscure department of British botany, describes about 556 species of *Fungi*, disposed in seventeen genera. Of these *Agaricus*, consisting of 282 species, is the principal. The distribution of the rest has been so much altered by following writers, and especially by Perfoon, that it would be useless to enter into any details concerning Withering's generic arrangement. The number of known British species is also greatly augmented since his time; so that perhaps they might be estimated between 750 and 800. A great part of them are figured in Sowerby and Bolton. This order is purposely excluded from the *English Botany*, because it would have overloaded the Cryptogamic department of that work. It has met with few votaries, as yet, in this country. In Germany the *Fungi* have received particular attention. See FUNGI.

Thus at the end of the Vegetable, like the Animal Kingdom, our knowledge vanishes amongst undistinguishable, almost imperceptible, tribes, whose confines blend with each other. The imperfection which we proudly attribute to such as we cannot understand, rather belongs to our own limited powers, or to our superficial enquiries. The accuracy and minuteness of investigation, amongst naturalists of the present day, so far transcends what was usual thirty years ago, that the cryptogamic class, like the insect tribes, has displayed a new world, as it were, to the curious enquirer, and has smoothed the way for succeeding observers; who in their turn need apprehend no deficiency of occupation or entertainment.

PLANTS, in *Agriculture*, vegetable productions, of which there are numerous kinds, such as herbs of various sorts, comprehending all the different grasses, leguminous vegetables, and esculents of other descriptions; trees, including those of the large or timber kind, and those of a more low or shrubby growth, whether under the name of shrubs, or under-shrubs. But properly, in an agricultural point of view, they chiefly comprehend such grasses or plants of that nature as are employed as the food of animals, and such trees or other plants as are capable of being applied to the purposes of timber, or made use of in the business of husbandry. And it may be farther observed with respect to plants, that most of them are hermaphrodite, containing the male and female parts in the same flower; others have flowers on the same stems, some of which are male, and others female. Some likewise produce flowers over the whole without being followed by any fruit, while others of the same sort bear fruit with flowers, in consequence of which they are distinguished into male and female plants. There are many of this sort, as the hop, hemp, and the poplar tree. The female flowers are only followed by fruit, the hermaphrodites, in respect to this, being considered among the female. Plants are capable of being fecundated from very considerable distances, which is a circumstance that the farmer should carefully keep in mind in sowing the seeds of particular sorts of plants, as all the cabbage tribe, and many others.

They require nourishment and air as well as animals to support, and keep them in a proper state of healthy growth, the former of which is principally drawn from the earth or the surrounding atmosphere. The gaseous materials are chiefly drawn from the atmosphere by the upper surfaces of their leaves, while the oxygen gas or *pure air* is given out during the sun-shine by their under surfaces. It is evident, therefore, that the means of support are provided in two different ways, by the radical or root fibres of the plant taking up one part and the leaves drinking up another, the former from the earth, and the latter from the air that surrounds them. See *FOOD of Plants*, and *MANURE*.

Most of the plants which are the principal objects of agriculture, are either raised and increased from the seeds, or the cuttings or other parts of roots, in the fields where they are to grow, as in all the grain and grass kinds, as well as in the potatoe; but there are a few in which the young plants, or offsets, are made use of, being set out in somewhat the garden method, and in which great care should constantly be taken that they are good in their kinds, and perfect in their nature and different parts. These are chiefly of the cabbage, madder, and other similar kinds.

What plants are likewise sometimes transplanted, but the practice is by no means in any degree of a general nature.

In regard to the plants of the tree kind, which are frequently a good deal employed, they are sometimes raised and provided from the seeds in the places where they are to

PLANTS.

grow; and at others reared and procured from the nursery grounds in the proper state for use in the forming of woods, plantations, and other sorts of wooded lands.

In the practice of planting, experience for a long time has sufficiently shewn, that where there is any degree of natural shelter or protection in the situation, and particularly where the ground has been properly prepared for the purpose, that such plants as have been transplanted in the nursery, and which are from a foot and a half to two or three feet in height, are the most suitable to be made use of in this intention. And it is directed by Mr. Loudon and others, that in performing the business, they should be placed from four to six feet distant from each other, being put into the soil in an irregular manner. But that in exposed situations and spots, where shelter and protection are only to be gained by putting them in in a thick or close method, or by that of planting nurseries, transplanted plants which are under a foot and a half in height should alone be had recourse to, being planted out from two feet and a half to four feet apart in such plantations. The space or distance between the plants in both these instances, must of necessity vary very greatly, according to the nature of the kind, and other circumstances. Also the borders and margins of large plantations, as well as narrow stripes and patches, ought to be thicker, or more closely planted with those sorts of plants, than the insides of great extents, though in the same exposures; but, on the contrary, where the ground is of a deep loamy quality, they may be put at wider distances, than where it is more thin and gravelly in its nature. Likewise in making very extensive plantations, it frequently becomes a matter of importance in setting out the plants, to place them in rows, as in this way they may be cultivated with much greater facility when they approach towards the growth of trees. For in many instances, the necessary cultivation, by such means, can be readily given with advantage by the plough and the horse-hoe; and not unfrequently different kinds of vegetables and roots may be introduced between the rows with great propriety and benefit, as those of the turnip, cabbage, onion, potatoe, carrot, and various other sorts.

It is contended that in all common plantations, the plants of these descriptions should be put into the ground with some degree of irregularity; but that wherever ornament is the least had in view, it should always be done in a manner, *irregularly irregular*; they should be grouped, or, in the more plain language of those engaged in the business, planted out just as if they had grown up by accident from the seed: or in such a manner as is seen in natural forests, where, in some parts, perhaps two or three trees appear to spring from one root, and in others quite thin and more detached. As by this means an endless variety of composition is produced, and at the same time an equal quantity of timber afforded, as the same would have yielded, if planted out in the most regular manner in respect to the distances. In proof of the truth of which, the above writer has adduced the common mode of thinning fields of young turnip plants, that have not sprung sufficiently thick. Some of the plants of which, it is asserted, may stand at two feet, others not above two inches separate from each other; but that wherever two are close together, by being unencumbered all round, they grow more vigorously than the others; and as the bulk swells, push each other asunder; so that in a short time the whole surface of the field is covered. The same thing, it is contended, takes place in natural woods. Suppose two spaces, containing twenty square yards each, and in each space two trees; but in one the trees to be planted three feet asunder, and the other three yards: when ten years growth has taken place, the bulk and height

produced upon each of the spaces would be exactly alike in every respect.

In regard to the methods of introducing or inserting the plants, in making plantations with them, they are in some measure different. The modes either by pitting them in or slit-planting are probably the best, as being the most generally practised; they may, however, be put in by the dibble, though it is a practice which can seldom be had recourse to with propriety or much success. With the pine and fir tribe of plants, the mode of planting is mostly considered as more cheap and expeditious, than that of sowing the seeds; but in raising large and extensive woods and forests, or other sorts of plantations, where most kinds of deciduous trees are required, and especially the oak and the ash, which should be the most generally grown, they ought to be produced from the seeds by sowing them in the situations where the plants are finally to remain and become trees. The seed of the oak put into the earth at the same time with a plant of the same kind five or six years old, will, it is supposed, over-top it in the course of seven years, and frequently sooner; besides, they are believed by some to last much longer, and ultimately to produce much better and more valuable timber. In all places where the ground is fully and properly prepared, and in which it is desirable to raise oak plants, for becoming trees, it will be found the best method to sow the seeds, as this can be done at less than a fifth of the expence of planting out the young plants, and besides, the trees will turn to advantage, either as timber or undergrowth much more expeditiously. And farther, as the oak is a particularly valuable sort of tree for its bark equally as well as for the timber, it ought to be universally raised; and were the above mode more generally attended to, there would be found a saving, even in the first place, of from three to four pounds the acre, which, to those who plant largely, would be of great consequence.

PLANTS, in *Gardening*, young living vegetables of any kind, which are raised or produced from a seed or in any other manner. Plants are of many different sorts and descriptions, as well as employed for a variety of different uses, and in a great diversity of intentions. They may, however, in the view of their garden culture, be principally considered as of the herbaceous, shrubby, and tree kinds, and as being annual, biennial, and perennial in their nature, and the time of their continuance.

Every plant may be said to consist of a root, that strikes down into the ground, or into some other body in some way or other, and which sends off numerous ramifications, which serve the purpose of fixing it in the earth or other situation, and at the same time to supply it with food or nourishment for its growth, increase, and continuance. There is likewise a stalk, stem, or trunk, which rises upwards into the atmosphere, and which is composed of a bark in the outer parts, a substance which is called *alburnum*, more internally a woody material, and a medullary matter, that is termed *pith*, in the inside of the whole. From this stem or trunk are formed and sent off the different branches and twigs, which contain the leaves and flowers, and which are very different in different sorts of plants. Besides which, all plants are furnished and provided with different sorts of vessels for conveying their sap, juices, and other kinds of fluids, and endued with several different powers, motions, and properties, which serve their different habits of growth, and the uses and intentions which they are to fulfil. See VEGETABLE, and VEGETATION.

The mode of growth and increase in plants, after they have been evolved and sprung up from seeds, or in any other

other manner, is described somewhat in this way by a late writer upon the structure and economy of plants; the root part of a plant at first advances more rapidly than the stem; as it has been found that an oak plant a foot and a half high has a root four feet in length, and that, if the principal root be in any way mutilated, the plant emits radicles in every direction; which always grow faster than if the root had remained perfect. Such radicles at first do not receive any considerable increase; but soon afterwards augment into a body almost equal to the principal root, and then protrude new radical shoots in a lateral direction. Also, that the roots are prolonged at the extreme apex or point, as will be perfectly evident, if any root be coloured with varnish or any other substance of a similar kind in different places; and it is, likewise, well known, that the radicles always shoot out in that part where the earth is the most humid, so that walls are not unfrequently thrown down or overturned by their power of penetrating towards moist places, or situations where the soil is the most soft in its nature.

But the trunk of a plant is expanded throughout its whole length; and not at the apex only, as in the case of the root; for if the tender stem of a plant, at the beginning of spring, be coloured over with varnish, or any other matter of the same kind, and marked in different places, the marks will, after a few months, be found to have receded in the several different parts when formed.

It is found that, in the growth, in an *annual* plant, the expansion of the stem in length continues until the explanation of the flowers has fully taken place; at which time the fibres that constitute the stalk, begin to grow hard, and to be indurated, and ultimately in a gradual manner to become dry and firm.

But in a *perennial* plant the increase of the stem continues until the leaves fall, or are destroyed in the autumnal season; during which time a germ or bud arises in the apex, in which the rudiment of the new stem, during winter, increases slowly until the following spring; when casting off its winter involucre, it continues the increase of the stem in the same way as the inferior part increased during the former year: for in that place where a bud is seated, a tumour extends, which is so continued with the new stem as scarcely to leave any vestige behind it.

It is remarked, that the increase of the stem in breadth does not arise from the dilatation of the ligneous or woody layers, but from the generation of new layers, which are annually deposited by the vessels of the bark. This is said to be fully explained and illustrated by the following experiments. "If the ring of the bark be torn from the trunk of a tree, and the ligneous cylinder of the naked part be perfectly surrounded with a leaf of tin, and the whole (after having replaced the cut-out ring of the bark) be covered with the tree plaster; then, upon cutting the tree some years after, it will appear that the ligneous cylinder, covered with tin, has received no increase, and that the tin, inserted between the ligneous cylinder and the new ligneous strata, is complete. These ligneous strata appear to be generated from the cortex; for if metallic threads be inserted obliquely into the cortex, they are after some years found in the wood itself, and not in the cortex or bark of the tree or plant."

It is shewn by attentive observation, that the trunk of a tree receives two ligneous or woody layers in the course of the year; but that the thickness of these layers is not the same every year; for it is the greatest when the tree is of a middle age, and the warmer the summer the more slender is the bark.

It would seem, that the bark is protruded by the vital

or living power of the vessels, which are placed in the wood of the tree or plant.

And the generation of the branches is supposed to be from the corona, or plexus of vessels, which is situated between the wood and medulla, or pith, from whence they proceed. Each germ or bud produces a new branch, so that it may be said to give birth to a new plant, which was shut up and laid concealed in that particular bud; for the branch contains every part which is essentially necessary to form a new plant, as is evident from cutting off a branch, and planting it in the ground, by which means a perfect tree or plant is produced, and soon grows up. The vessels, it is believed, principally protrude where there is the least resistance in the bark, as in the axilla of the leaves, the nodes, and the joints; the same is noticed in respect to the branches of the root, and explains the reason, why the propagation of plants does not succeed by the slip or branch, unless a node, joint, or germ remain in them. Also why, if a branch of a tree or plant, that is yet adhering to it, be plastered or covered round with earth or moist dung, there proceeds from it a root into these substances. And why the ancients falsely attributed the generation or production of boughs to the medulla or pith of the tree; as in trees which are destitute of this substance, it is seen that no branches are produced or brought forth.

Further, the generation or production of leaves in plants originates from the vessels of the bark only; for, the bark being separated from the wood, no connection of the leaves with the wood can be observed; and the bark alone, if put into water, produces leaves.

Lastly, in the generation or production of the flowers of plants, the exterior bark, or epidermis, would seem to proceed into the cups, the alburnum into the corolla, and the series of vessels into the other parts of them.

Plants are likewise found to be of very different kinds and qualities, in respect to their powers of bearing fruit, or of becoming prolific, as well as that of their differing in so many other particulars, as in their natures, modes of growth, and various other points of consequence.

Many of them have the male and female parts in the same individual flower, whence they are commonly denominated hermaphrodite plants; and there are others, which have the male and female flowers in a state of intermixture on the same stem or branch, as is the case with the cucumber and melon, as well as some other kinds of plants. Some have also the flowers all over them without any fruit being produced, while others of the same kind, at the same time, have flowers, and produce fruit, which afford the distinction of male and female plants. But as those of the female sort only produce fruit, those of the first mentioned kind are constantly considered to be of this nature.

A perfect knowledge of these circumstances is of great advantage in the business of practical gardening, as it can be applied to many useful purposes in providing fruit, as well as good seeds of different kinds.

Much of the labour and attention of the horticulturist is likewise employed in the raising and providing plants of the herbaceous kind, which are extremely numerous, and not a few of them of considerable importance, in the view of food, requiring to be cultivated and produced in a regular and constant manner. They differ greatly, however, in their natures and qualities, as well as in their management and means of production. There are some, which have but little stem, being chiefly of a leafy description; others, in which the same part is far more considerable, but of a fleshy, tender nature; and still others in which the stalks are tough, hard, and of rather a ligneous quality.

Whenever herbaceous plants of any of these kinds are to be raised, it is almost constantly done from the young plants, after they have had some little growth from the seeds, and are in a perfect condition in every respect. This method is pursued in all the different kinds of cabbages, cauliflowers, brocolies, and lettuces, as well as with endive, celery, and many others. But there are some which are raised from seeds without being transplanted in the above manner, and a few from offsets or slips, and by dividing the roots or other parts.

In the shrubby and tree kinds, the plants are mostly increased from seeds, cuttings, layers, and slips.

All plants possess, by means of their living principles, the proper and necessary degrees of heat, by which they vegetate, increase, and are enabled to resist the overabundant cold or heat, which may at any time surround them; but they differ very materially in this respect, some having a much greater power of doing it than others. There are some which have also a remarkable capability of resisting cold in their roots; and others, which are equally remarkable in resisting heat. The kidney bean is an example of the former kind, and that of the cucumber of the latter: for if a green leaf of the former vegetable be introduced into the frozen juice of spinach, it quickly becomes thawed; and if a vessel full of water be exposed in a bed of cucumbers, the water speedily becomes warm, but the cucumbers remain cold to the touch; and if one be eaten the stomach is found to be cooled, as if it had taken ice. And the same thing has been found in respect to fruits, while growing upon the trees. The state of heat in plants would therefore seem to proceed from the matter of heat, which is taken from the surrounding air; and hence it is, that the shades of all sorts of trees are so cooling in their nature.

PLANTS, Fossile. Many species of tender and herbaceous plants are found at this day, in great abundance, buried at considerable depths in the earth, and converted, as it were, into the nature of the matter they lie among; fossile wood is often found very little altered, and often impregnated with substances of almost all the different fossile kinds, and lodged in all the several strata, sometimes firmly imbedded in hard matter, sometimes loose: but this is by no means the case with the tenderer and more delicate subjects of the vegetable world. These are usually immersed either in a blackish slaty substance, found lying over the strata of coal, or else in loose nodules of ferruginous matter of a pebble-like form, and they are always altered into the nature of the substance they lie among: what we meet with of these are principally of the fern kind: and what is very singular, though a very certain truth, is, that these are principally the ferns of American growth, not those of our own climate. The most frequent fossile plants are the polypody, spleenwort, osmund, trichomanes, and the several larger and smaller ferns; but beside these there are also found pieces of the equisetums, or horse-tails, and joints of the stellated plants, as the clivers, madder, and the like; and these have been too often mistaken for flowers; sometimes there are also found complete grasses, or parts of them, as also reeds and other watery plants; sometimes the ears of corn, and not unfrequently the twigs or bark, and impressions of the bark, and fruit of the pine or fir kind, which have been, from their scaly appearance, mistaken for the skins of fishes; and sometimes, but that very rarely, we meet with mosses and sea-plants.

Many of the ferns not unfrequently found, are of very singular kinds, and some species yet unknown to us; and the leaves of some appear set at regular distances, with round protuberances and cavities. The stones which contain

these plants split readily, and are often found to contain, on one side, the impression of the plant; and on the other the prominent plant itself: and, beside all that have been mentioned, there have been frequently supposed to have been found with us ears of common wheat, and of the maize or Indian corn; the first being in reality no other than the common endmost branches of the firs, and the other the thicker boughs of various species of that and of the pine kind, with their leaves fallen off; such branches in such a state cannot but afford many irregular tubercles and papillæ, and, in some species, such as are more regularly disposed.

These are the kinds more obvious in England; and these are either immersed in the slaty stone which constitute whole strata, or in flattened nodules, usually of about three inches broad, which readily split into two pieces on being struck.

They are most common in Kent, on coal-pits, near New-castle, and the forest of Dean, in Gloucestershire; but are more or less found about almost all our coal-pits, and many of our iron-mines.

Though these seem the only species of plants found with us, yet in Germany there are many others, and those found in different substances. A whitish stone, a little harder than chalk, frequently contains them; they are found also often in a grey slaty stone, of a firmer texture, not unfrequently in a blackish one, and at times in many others; nor are the bodies themselves less various here than the matter in which they are contained; the leaves of trees are found in great abundance, among which those of the willow, poplar, whitethorn, and pear-trees, are the most common; small branches of box, leaves of the olive-tree, and stalks of garden thyme, are also found there; and sometimes ears of the various species of corn, and the larger as well as the smaller mosses in great abundance.

These seem the tender vegetables, or herbaceous plants, certainly found thus immersed in hard stone, and buried at great depths in the earth: others of many kinds there are also named by authors; but as in bodies so imperfect, errors are easily fallen into, these seem all that can be ascertained beyond mere conjecture. Hill's Hist. of Fossils. See PETRIFICATION.

PLANTS, Marine. See SEA-PLANTS.

PLANUM, Os, in *Anatomy*, the smooth orbital plate of the ethmoid bone. See CRANIUM.

PLAPPERT, in *Commerce*, a money of account in Switzerland; 15 plapperts, or skillings, being = 12 groschen, or gros, = 10 Swiss batzes = 9 good batzes = 1 livre, and containing 36 creutzers = 90 rappen = 180 pfenings.

PLAQUET, in *Ancient Armour*, a plate which was occasionally added to the breast-plate, in order to strengthen it.

PLAS, in *Biography*, two brothers, born in Spain, celebrated performers on the hautbois, who, like the two Bezozzis of Turin, always lived, practised, and performed together, as one and the same being. They left Madrid in 1752, and arrived at Paris the same year, where their performance excited equal wonder and extacy. Their tone, expression, taste, and execution, were as exactly similar as double stops on the same instrument.

In 1761 they went into Germany, and were engaged in the chapel of the duke of Wirtemberg, and in his household as chamber musicians.

PLASCHKEN, in *Geography*, a town of Prussian Lithuania; 9 miles N.W. of Tilit.

PLASEMBURG, a town of Transylvania, near Hermanstadt.

PLASENCIA, or PLACENCIA, a town of Spain, in the province of Guipuzcoa; 20 miles N. of Vittoria.

PLASENCIA,

PLASENCIA, a town of Spain, in the province of Estramadura, situated in the middle of mountains, in a narrow valley, tolerably fertile, nine leagues long, and watered by the river Xerte. The town stands on the banks of this river, and is partly surrounded by it, as if in a peninsula. Its situation is also embellished by an agreeable promenade. Plafencia is a suffragan of San Jago, and its diocese comprehends a cathedral, chapter, and 152 parishes. This town is the chief place of a corregidoret, and contains seven parish churches, three convents of monks, and several chapels or oratories. Here is a fine aqueduct, which conveys water from the distance of two leagues, and has upwards of 80 arches; 95 miles W.S.W. of Madrid. N. lat. 40° 3'. W. long. 5° 9'.

PLASH, in *Rural Economy*, the bough or stem which is laid down by means of a nick or cut being made on the upper side of it, in repairing or restoring old hedge-fences.

PLASHER, a person of the labouring kind, whose business is the making or repairing of hedge-fences by means of plashing.

PLASHING of hedges, the operation or process by which this sort of work is performed in restoring old run up open hedges. The usual mode of executing it is as follows; the stronger stems are selected, at as regular distances as possible, and generally at about thirty inches apart. These are called the stakes; and are commonly headed over at four or five feet above the surface, according to the general strength of the hedge in question, so as they may all range in line, and at one height. The more pliable branches and small twigs are interwoven, in the basket manner, among the stakes, from top to bottom, as closely as possible. Such as will not bend in a pliable manner, and afterwards remain in due position, are snagged half through with the bill, to make them more obedient. The strong stems that cannot be laid in, and are not wanted for stakes, are cut close by the surface. In places where stems strong enough, and fit for stakes, are wanting, the deficiency is supplied by dead stakes. After the plashing is finished, the hedge is dressed smooth on both sides with the bill, or some other similar instrument. This is a method that is much practised in Hertfordshire and some other counties. See FENCE.

The principal objection to this mode, which is certainly the cheapest and most easily performed, is, that the stakes, or cut-over stems, shoot forth strongly to the detriment of the under part of the hedge, which, by over-shadowing, they retard in growth, and keep naked of spray; and which probably suggested an improvement, which is that of cutting none over at all, but weaving in the tops of the stakes along with the plashes. The propriety of this mode is at once evident; for, besides that the above complaint cannot possibly attach, the stems cut by the surface send up a strong growth, which, intermixing with the plashes, renders the whole more close and impenetrable than would otherwise be the case.

In cases where two rows of quicks have been planted, according to the common method, at the distance of a foot from each other, the *back* row being plashed in some of the above modes, and the front one being cut down to the stub, would be the most effectual method of preserving the present, and producing a new fence. It is, however, conceived, that this operation can only be effectually and *handsomely* performed in cases where there is a good portion of spray and long pliable shoots or branches; and when the edge has, if not youth, at least vigour on its side, to send forth a luxuriant growth, and cover the naked appearance the plashes would otherwise have. And that for the more handsome performance of this business, there is also a season

more suitable than another, which is the fall, or beginning of winter, as at this season the shoots are more pliable than in spring, when the sap begins to rise and circulate; at which time the shoots of all plants are most brittle. After the hedge is plashed, the ditch, provided there be one, should be scoured out, and dressed up; and that where the fence is properly attended to, in regard to pruning and cutting, it may last for many years.

The manner of executing this sort of work in the Hertfordshire mode has been fully explained in speaking of the nature of restoring fences.

This sort of practice is sometimes necessary to be had recourse to in gardens where the outward fences have been suffered to run up in rude growth, naked and open at the bottoms; they being reformed and reduced to order by proper trimming, thinning, cutting, and laying down the general stems and branches in a slanting manner lengthways, according to the ranges of the hedges, being interwoven between other stems which are left upright; the work being assisted by suitably nicking, cutting, or gashing the different parts on their upper sides; and the whole of the smaller lateral branches being plashed in, so as to close all the lower vacancies, and thicken every part regularly from the bottom to the top, to the height of from three to four feet, or a little more, according to circumstances.

This process is occasionally performed to any kind of deciduous common hedges, such as those of white-thorn, black-thorn, elm, poplar, beech, or other sorts; and in proceeding in the work, it is frequently necessary, especially in very disorderly rough edges, previously to trim or lop off much of the outward and over-growing rude branches of them, as well as the large naked wood and obviously superabundant growths, both above and below; carefully bringing down such branches or other parts as are left in an exact and regular manner, plash after plash, until the whole business is finished.

PLASM, **PLASMA**, is sometimes used for a mould, wherein any metal, or such like running matter, which will afterwards harden, is cast to receive its figure.

PLASO, in *Botany*, Rheede Hort. Mal. v. 6. 29. t. 16, 17, is a very noble papilionaceous and leguminous shrub, or tree, referred by Lamarck to *Erythrina*, with the specific name of *monosperma*. Jussieu, Gen. 357, mentions it under that genus, with a hint, extremely well founded, of its probably constituting a new one. Of this the celebrated Danish botanist, Koenig, who gathered in India two species of the genus in question, was aware. He named it *Butea*, after that distinguished lover of botany, the first earl of Bute; either not knowing, or not recollecting, that another genus was called *Stuartia* by Linnæus, in honour of this nobleman, and was universally received under that denomination. Dr. Roxburgh has however published the *Butea*, and it is adopted by Willdenow, Sp. Pl. v. 3. 917, as well as in Ait. Hort. Kew. v. 4. 252, and by the late Rev. Mr. Wood, in our 5th vol. See **BUTEA**.

The name is altogether inadmissible on the ground above mentioned, one genus being abundantly sufficient to commemorate any one person whatever, nor has there ever been a similar example, among classical writers of the Linnæan school. *Butea* may nevertheless remain as a memorial of the late marchioness of Bute, who paid much attention to botany, and is mentioned as having introduced several plants from the gardens of Madrid, into those of England.

PLASS, in *Geography*, a town of Bohemia, in the circle of Rakonitz; 18 miles S.W. of Rakonitz.

PLASSEY, a town of Hindoostan, in Bengal, near

which colonel Clive defeated the troops of Surajah Dowlah in 1757; 25 miles S. of Moorshedabad.

PLASTER, or **PLASTER**, in *Building*, a composition of lime, sometimes with hair, sometimes with sand, &c. to parget or cover the nudities of a building.

There is also a plaster of a coarser sort than the plaster of Paris, which is sometimes used in this country for floors in gentlemen's houses, and for corn-granaries: it is made of a bluish stone, taken out of quarries, which are generally at the side of a hill, much like the stone of which Dutch terraces is made: the stone is burnt like lime, becomes white by burning, and when mixed with water, does not ferment like lime: when cold, it is beat into a fine powder; and when it is used, the quantity of about a bushel is put into a tub, and water applied to it, till it becomes liquid: in this state it is well stirred with a stick, and used immediately; for in less than a quarter of an hour it becomes hard and good for nothing, as it will not bear being mixed a second time like lime. See **GYP-SUM**, and **PLASTERING**.

PLASTER, in *Pharmacy*, an external application of a harder consistence than our ointments: these are to be spread according to the different circumstances of the wound, place, or patient, either upon linen or leather.

If the part upon which they are to be laid be naturally hairy, it must be shaved; but that they may stick the better, the natural shape of the part must be consulted, and the plaster spread and formed accordingly, either round, square, triangular, elliptical, in a lunar form, or in shape of the letter T. Some also are divided at both ends, and others are perforated in the middle: these last are of frequent use in fractures attended with a wound; for by this contrivance the wound may be cleansed and dressed without removing the plaster.

Indeed there is almost no part of the body which a plaster of one of those forms may not be made to serve for, if it be notched about the edges with a pair of scissors. See **EMPLASTRUM**.

The use of plasters is various; they are serviceable in securing the dressings, they also forward the maturation of the pus, agglutinate and heal wounds, unite broken bones, heal burns, alluage pain, and strengthen weak parts. In many instances they contain acrid and stimulating substances, and operate as rubefacients, or blisters.

The calces or oxyds of lead boiled with oils, unite with them into a plaster of a proper consistence, which makes the basis of several other plasters: but some of them owe their consistence to wax and resin; and others contain no oily or fatty matter whatever: in boiling these compositions, a quantity of hot water must be added from time to time, to prevent the plaster from burning and growing black; but this should be done with care, lest it cause the matter to explode.

Plasters should not adhere to the hand when cold; they should be easily spread when heated; and after they are spread they should remain tenacious and pliant; but they should not be so soft as to run when heated by the skin. All plasters become too consistent or brittle when long kept; but in this case, those which are unctuous may be remelted by a gentle heat, and some oil added to them. They are usually formed into rolls, each of which is wrapped in paper, and when used, they are melted, and spread on leather, calico, linen, or silk. Those that contain metallic oxyds ought to be melted by boiling water, for in a greater degree of heat the fatty matter is apt to reduce the oxyd.

PLASTER, *Adhesive*. See **EMPLASTRUM**.

PLASTER, *Ammoniac*, is formed by dissolving 5oz. of

purified ammoniac in half a pint of acetic acid (distilled vinegar), and evaporating the solution in an iron vessel placed in a water bath; constantly stirring it till it acquire a proper consistence. This plaster, which is stimulant and resolvent, is applied to scrophulous humours, and white swellings, and sometimes over the scalp, in tinea capitis.

PLASTER, *Ammoniac, with Mercury*. See **EMPLASTRUM**.

PLASTER, *Anodyne*. See **EMPLASTRUM**, and **PLASTER of Opium**, infra.

PLASTER, *Aromatic*, is formed, according to the directions of the Dublin pharmacopoeia, of frankincense, 3 oz.; yellow wax, $\frac{1}{2}$ oz.; cinnamon bark in powder, 6 dr.; oil of pimenta and oil of lemons, of each 2 dr. Melt the frankincense and the wax together, and strain the mixture; when it thickens by cooling, mix with it the powder of cinnamon previously rubbed with the oils, and form them into a plaster. This plaster is an elegant stimulant, and applied to the region of the stomach in dyspepsia, and increased irritability of that viscus, allays pain and vomiting, and expels flatus. As the oils are very volatile, it must be spread by the thumb without being melted. It requires to be frequently renewed, and is not very adhesive.

PLASTER, *Assafetida*, consists, by the Edinb. pharm., of plaister of semi-vitreous oxyd of lead, and assafetida, of each two parts, and galbanum and yellow wax, of each one part. This plaster is sometimes applied over the umbilical region, in flatulence and hysteria.

PLASTER, *Blistering, Emplastrum Lyttæ* of the Lond. pharmac., is made by melting $1\frac{1}{2}$ lb. of wax plaster with a pound of prepared lard, and after removing them from the fire, when the mixture is beginning to be solid, sprinkling in 1lb. of blistering flies reduced to a very fine powder, and mixing the whole together. The *emplastrum Meles vesicatorii*, olim, *emplastrum vesicatorium* of the Edinb. pharm., consists of mutton suet, yellow wax, resin, and blistering flies, of each equal weights. Reduce the insects to a fine powder, and mix them with the other articles, previously melted together, and removed from the fire. The *emplastrum cantharidis* of the Dubl. pharmac. is formed by melting purified yellow wax and mutton suet, of each a pound, and 4 oz. of yellow resin together, and a little before they concreate in becoming solid, sprinkling in 1 lb. of blistering flies in fine powder, and forming the whole into a plaster. (See **EMPLASTRUM**.) Blistering plasters should remain applied at least for twelve hours to raise a perfect blister; they are then to be removed, the vesicle is to be cut at the most depending part, and without removing the cuticle, the vesicated part is to be dressed with simple cerate, or spermaceti ointment; and the old cuticle allowed to remain until a new one is formed under it; when it peels off, and the whole is healed in the course of a few days. The application of these plasters is sometimes attended with strangury and bloody urine, from the absorption of the active principles of the insect, and the irritation of the kidneys and urethra; and this effect is much increased, if the blister be applied over an abraded surface, e.g. on the head after it has been immediately shaved, and also if the plaster has remained too long applied. To prevent strangury, it has been recommended to mix camphor with the blistering composition, but this has no good effect; it is better obviated by copious dilution with milk, or mucilaginous fluids, and fomentations of warm milk and water to the blistered part, after the removal of the plaster. When the head is to be blistered, it should be shaved at least ten hours before the plaster is applied; and in all cases it is expedient to interpose a piece of thin gauze between the vesicatory and the skin, wetted with vinegar, and applied smooth and very close over the plaster.

plaster. When the blistered part becomes a spreading sore, which is sometimes the case in irritable habits, the best local application is a warm emollient poultice, and bathing the denuded surface frequently with tepid milk and water; while at the same time cinchona bark is internally administered. See **BLISTER**.

PLASTER of Spanish flies, compound, of Edinb. pharm., is prepared of 18 parts of Venice turpentine; Burgundy pitch and blistering flies, of each 12 parts; yellow wax, 4 parts; subacetite of copper, 2 parts; white mustard seeds and black pepper, of each 1 part. Melt the Burgundy pitch and the wax, and add to them the turpentine; while these remain still warm, after being melted, sprinkle in the other ingredients reduced to fine powder, and mix them, stirring constantly, so as to form a plaster. This plaster is intended to raise a blister more quickly than the former, and is therefore adapted to cases of gout and cramps of the stomach, in which the effect of the blister must be almost instantly produced. Its operation is attended with much pain and pungent sense of heat; and it is apt to produce very unpleasant ulceration if allowed to remain too long applied.

PLASTER, Cephalic. See **EMPLASTRUM Cephalicum**.

PLASTER, Common. See **EMPLASTRUM Commune**.

PLASTER, Cumin. See **EMPLASTRUM à Cymino**. This plaster is stimulant and discutient; and is applied to the hypogastric region in flatulence and a cold feeling of the bowels, and to indolent tumours.

PLASTER, Drawing. See **EMPLASTRUM Attrahens**.

PLASTER of Galbanum, Compound, of the Lond. pharm., is composed of purified galbanum, 8 ounces; plaster of lead, 3 pounds; common turpentine, 10 drachms; and resin of the spruce fir powdered, 3 ounces. Having melted the galbanum and the turpentine together, mix in first the resin, and then the plaster of lead previously melted by a slow fire, and mix the whole together. The plaster of galbanum of the Dub. pharm. is prepared by adding to $\frac{1}{2}$ lb. of galbanum melted by heat, 2 lbs. of litharge plaster, and 4 oz. of yellow wax sliced; and then melting the whole together by a gentle heat.

PLASTER, Gum, of Edinb. ph., is composed of 8 parts of plaster of semi-vitreous oxyd of lead, and ammoniac gum-resin, galbanum, yellow wax, of each 1 part. See **EMPLASTRUM Gummi**.

These plasters are stimulant and suppurative. They are applied with advantage to serophulous tumours; to joints which have been long affected with arthritic pains; and to the loins in rickets. As a suppurative, they are applied to indolent tumours, and to reduce the induration which often remains round abscesses, after they are discharged.

PLASTER, Mercurial. (See **EMPLASTRUM commune cum Mercurio**.) The Edinb. pharm. directs it to be prepared of olive oil and resin, of each 1 part; mercury, 3 parts; plaster of semi-vitreous oxyd of lead, 6 parts; rub the mercury with the oil and the resin, previously melted together and cooled, until the globules disappear; then add gradually the plaster of semi-vitreous oxyd of lead melted, and let the whole be carefully mixed together. These plasters are powerful discutients, and are applied to buboes, venereal tumours, nodes when they are not very painful to the touch, and indurations; they are also applied to joints affected with obstinate syphilitic pains.

PLASTER of Opium, consists of hard opium powdered, $\frac{1}{2}$ oz.; resin of the spruce fir powdered, 3 oz.; lead plaster, 1 lb.: melt the plaster and the resin together, then add the opium, and mix the whole. This plaster is said to be anodyne, and useful in relieving rheumatism and local pains.

PLASTER of red oxyd of Iron of Edin. pharm., formerly

strengthening plaster, is composed of plaster of semi-vitreous oxyd of lead, 24 parts; resin, 6 parts; yellow wax and olive oil, of each 3 parts; and red oxyd of iron, 8 parts; rub the red oxyd of iron with the oil, and add the other ingredients melted.

PLASTER of Frankincense of Dubl. pharm. is formed of litharge plaster, 2 lbs.; frankincense, $\frac{1}{2}$ lb.; and red oxyd of iron, 3 oz.; to the frankincense and plaster melted together add the oxyd, stirring them together so as to form a plaster. These plasters are supposed to be tonic; and are used in muscular relaxations, and weaknesses of the joints after sprains; but they act chiefly in affording a mechanical support to the parts. See **EMPLASTRUM Roborans**.

PLASTER, Compound pitch, is composed of dried pitch, 2 lbs.; frankincense, 1 lb.; yellow resin and yellow wax, of each 4 oz.; and expressed oil of nutmeg, 1 oz. To the pitch, resin, and wax, melted together, add first the frankincense, then the oil of nutmeg, and mix the whole. This plaster is stimulant and rubefacient. It is used in catarrh, and other pulmonary affections, applied to the thorax; and in head-ache, and chronic ophthalmia, applied to the temples. When a serous exudation takes place, the plaster should be frequently renewed.

PLASTER, Head, is prepared by boiling together over a slow fire, of semi-vitreous oxyd of lead, rubbed to a very fine powder, 5 lbs.; olive oil, a gallon; water, 2 pints, stirring constantly until the oil and oxyd of lead cohere into the consistence of a plaster. It is necessary, however, to add a little boiling water, if the whole of that which was employed at first shall be consumed before the end of the process.

PLASTER of semi-vitreous oxyd of Lead, formerly common plaster, is prepared of the semi-vitreous oxyd of lead, 1 part; and olive oil, 2 parts; having added some water, boil them, stirring constantly, until the oil and the oxyd unite into a plaster. See **EMPLASTRUM**.

PLASTER, Litharge, of Dub. ph., is prepared by mixing 5 lbs. of litharge in fine powder; 9 lbs. of olive oil, and 2 pints of boiling water, at a high temperature, constantly stirring until the oil and the litharge unite so as to form a plaster, supplying occasionally any waste of water that may take place. These plasters are intended chiefly to defend excoriated surfaces from the action of the air, and to form the basis of some other plasters.

PLASTER, Resin, is formed of yellow resin, $\frac{1}{2}$ lb., and lead plaster, 3 lbs.; melt the lead plaster by a gentle heat; then add the resin in powder and mix.

PLASTER, Resinous, formerly adhesive plaster, is composed of plaster of semi-vitreous oxyd of lead, 5 parts, and resin, 1 part.

PLASTER with Resin, Litharge, is formed by melting $3\frac{1}{2}$ lbs. of litharge plaster by a moderate heat, and adding $\frac{1}{2}$ lb. of yellow resin finely pulverized, that it may melt quickly, and form a plaster. (See **EMPLASTRUM Adhesivum**.) These plasters are defensive, adhesive, and gently stimulant; they are used for retaining together the lips of recent wounds, when it is proposed to heal them by the first intention; to give support to ulcerated parts; and to assist their granulation and cicatrization.

PLASTER, Soap. (See **EMPLASTRUM Saponis**.) The soap plaster of the Edinb. pharm. is composed of 4 parts of semi-vitreous oxyd of lead; 2 parts of gum plaster, and 1 part of soap sliced. Mix the soap with the plasters melted together; then boil them a little so as to form plaster. Soap plaster is discutient, and is applied to lymphatic tumours; but it is much less useful than the mercurial plaster.

PLASTER, Stomachic. See **EMPLASTRUM Stomachicum**.

PLASTER,

PLASTER, Warm, is made by melting together, over a gentle fire, one ounce of gum plaster, and two drachms of blistering plaster; or one part of plaster of cantharides, and seven parts of Burgundy pitch, according to the Dublin pharmacopeia. This is useful in catarrh, hooping-cough, the sciatica, and other fixed pains of the rheumatic kind. It ought, however, to be worn for some time, and to be renewed, at least, once a week.

PLASTER, Wax, is formed by melting together of yellow wax and of prepared suet, of each three pounds; and yellow resin a pound; and then straining. The *simple plaster*, formerly *wax plaster* of Edinburgh pharmacopeia, is formed of yellow wax, three parts; mutton suet and resin, of each two parts. These were generally used instead of the melilot plaster, as a proper application after blisters, and in other cases where a gentle digestion is necessary; but on account of the pain and irritation they occasion, they are now seldom employed.

PLASTER of Paris, is a fossile stone, serving many purposes in building; and used likewise in sculpture, to mould and make statues, basso relievos, and other decorations in architecture.

It is dug out of quarries, in several parts of the neighbourhood of Paris; whence its name. The finest is that of Montmartre. See GYPSUM.

Plaster of Paris, among our workmen, is of two kinds, viz. *crude*, or in the stone, and *burnt*, or beaten.

The *crude* is the native plaster, as it comes out of the quarry; in which state it is used as shards in the foundations of buildings.

The *burnt* plaster is a preparation of the former, by calcining it like lime in a kiln or furnace, and then beating it into powder, and diluting and working it. In this state it is used as mortar, or cement, in building.

This, when well sifted, and reduced into an impalpable powder, is used also to make figures, and other works of sculpture; and is, besides, of some use in taking out spots of grease, &c. in stuffs and silks.

The method of representing a face truly in plaster of Paris is this: the person, whose figure is designed, is laid on his back, with any convenient thing to keep off the hair. Into each nostril is conveyed a conical piece of stiff paper, open at both ends, to allow of respiration. These tubes, being anointed with oil, are supported by the hand of an assistant; then the face is lightly oiled over, and the eyes being kept shut, alabaster fresh calcined, and tempered to a thinish consistence with water, is by spoonfuls nimbly thrown all over the face, till it lies near the thickness of an inch. This matter grows sensibly hot, and in about a quarter of an hour hardens into a kind of stony concretion; which being gently taken off, represents, on its concave surface, the minutest part of the original face. In this a head of good clay may be moulded, and therein the eyes are to be opened, and other necessary amendments made. This second face being anointed with oil, a second mould of calcined alabaster is made, consisting of two parts joined lengthways along the ridge of the nose; and herein may be cast, with the same matter, a face extremely like the original.

If finely powdered alabaster, or plaster of Paris, be put into a basin over a fire, it will, when hot, assume the appearance of a fluid, by rolling in waves, yielding to the touch, steaming, &c., all which properties it again loses on the departure of the heat; and being thrown upon paper, will not at all wet it, but immediately discover itself to be as motionless as before it was set over the fire; whereby it appears, that a heap of such little bodies as are neither

spherical, nor otherwise regularly shaped, nor small enough to be below the discernment of the eye, may, without fusion, be made fluid, barely by a sufficiently strong and various agitation of the particles which compose it; and, moreover, lose its fluidity immediately upon the cessation thereof.

Two or three spoonfuls of burnt alabaster, mixed up thin with water, in a short time coagulate, at the bottom of a vessel full of water, into a hard lump, notwithstanding the water that surrounded it. Artificers observe, that the coagulating property of burnt alabaster will be very much impaired or lost, if the powder be kept too long, especially if in the open air, before it is made use of; and when it hath been once tempered with water, and suffered to grow hard, they cannot, by any burning or powdering of it again, make it serviceable for their purpose as before. Boyle's Works Abr. vol. i. p. 133. 313. 341.

This matter, when wrought into vessels, &c. is still of so loose and spongy a texture, that the air has easy passage through it. Mr. Boyle gives an account, among his experiments with the air-pump, of his preparing a tube of this plaster, closed at one end and open at the other, and on applying the open end to the cement, as is usually done with the receivers, it was found utterly impossible to exhaust all the air out of it; for fresh air from without pressed in as fast as the other, or internal air, was exhausted, though the sides of the tube were of a considerable thickness. A tube of iron was then put on the engine; so that being filled with water, the tube of plaster of Paris was covered with it; and on using the pump, it was immediately seen, that the water passed through into it as easily as the air had done, when that was the ambient fluid. After this, trying it with Venice turpentine instead of water, the thing succeeded very well; and the tube might be perfectly exhausted, and would remain in that state several hours. After this, on pouring some hot oil upon the turpentine, the case was much altered; for the turpentine melting with this, that became a thinner fluid, and in this state capable of passing like water into the pores of the plaster. On taking away the tube after this, it was remarkable that the turpentine, which had pervaded and filled its pores, rendered it transparent, in the manner that water gives transparency to that singular stone called *oculus mundi*. In this manner, the weight of air, under proper management, will be capable of making several sorts of glues penetrate plaster of Paris; and not only this but baked earth, wood, and all other bodies porous enough to admit water on this occasion. Phil. Transf. N° 122.

Plaster of Paris, diluted with water into the consistence of a soft or thin paste, quickly sets or grows firm, and at the instant of its setting, has its bulk increased; for Mr. Boyle has found, that a glass vessel, filled with the fluid mixture, and closely stopped, bursts while the mixture sets, and sometimes a quantity of water issues through the cracks.

This expansion of the plaster, in passing from a soft to a firm state, is one of its valuable properties; rendering it an excellent matter for filling cavities in foundry works, where other earthy mixtures would shrink and leave vacuities, or entirely separate from the adjoining parts.

It is probable also, that this expansion of the plaster might be made to contribute not a little to the elegance of the impressions which it receives from medals, &c. by properly confining the soft matter, that its expansion may force it into the minutest traces of the figure; the expansion of the matter doing the same office as the pressure by which the wax is forced into the cavities of a seal.

Plaster of Paris promotes the fusion of forged iron.

This substance is commonly used for taking casts and impressions from figures, busts, medals, &c. as it is adapted to the double use of making both casts and moulds for forming them. See *Impressions of MEDALS*.

PLASTER of Paris, in *Agriculture*, a substance of the calcareous kind, in combination with the vitriolic acid, which has been sometimes made use of as a manure. See GYPSUM and Sulphate of LIME.

PLASTER, in *Gunnery*, a piece of greased leather or rag, used by riflemen, &c. to make the ball fit the bore of the piece.

PLASTER Floors, in *Rural Economy*, such floors as are constituted of plaster, prepared from such lime as possesses a strong binding property. They are highly useful in cottages and farm-houses, as affording much security against fire. In constructing them, it is observed, in the first volume of Communications to the Board, that the joists are laid in the usual manner; after which a sort of strong reed, which is found in Huntingdonshire, is nailed on, upon which the plaster is applied; but in order to save it, there is frequently a thin coat of common lime laid on first, to fill up the crevices and inequalities. On this the plaster is then spread out, to the thickness of about two inches, being laid on with as much expedition as possible. The plaster is sold at the kilns in the midland districts, at 6*d.* the bushel: and the expence of laying it on, if burnt and prepared, is 5*d.* the square yard; but if to be burnt and prepared by the workmen, about as much more. The floors are said to be excellent and cheap. Where reeds cannot be procured, laths may be made use of, but they come much higher. Floors of this sort are much in use in Nottinghamshire, as well as in Rutlandshire, at the earl of Winchelsea's, where the upper floors of his farm-houses are made of it.

These kinds of floors should be more attended to, in constructing small houses both of the cottage and other kinds, as being cheap, readily laid, and at the same time secure.

PLASTERING, in *Architecture*, is that operation which consists in laying on coats of mortar, variously prepared, on the ceilings and walls, &c. of different buildings. This belongs to a class of artificers called plasterers. See PLASTER.

Plasterers' work is of two kinds: namely, ceiling, which is plastering upon laths; and rendering, which is plastering upon walls. These are measured separately. The contents are estimated either by the foot, or yard, or square of 100 feet. Enriched mouldings, &c. are rated by running or lineal measure. Deductions are to be made for chimnies, doors, windows, &c. But the windows are seldom deducted, as the plastered returns at the top and sides are allowed to compensate for the window opening.

It were much to be wished that this art of plastering could be again brought to its ancient perfection. In our best buildings the plastered walls and ceilings crack and fly, and in a little time grow damp, or moulder to decay.

The Romans had an art of rendering their works of this kind much more firm and durable, and there is no reason to despair of reviving this art by proper trials.

The ancient plastering of these people preserved to this time, where it has not met with violent blows or injuries from accidents, is still found as firm and solid, as free from cracks or crevices, and as smooth and polished on the surface, as if made of marble. The bottoms and sides of the Roman aqueducts were made of this plastering, and endured many ages without hurt, unless by accidents: witness that whereof some yards are still to be found on the top of the Pont de Gard, near Nismes, for the support of which that

famous bridge was built to carry water to the said town. The roofs of houses, and the floors of rooms, at Venice are covered with a sort of plaster, made of later date, and yet strong enough to endure the sun and weather for several ages, without cracking or spoiling, and without much injury from people's feet.

The secret of preparing this Venetian plaster is not among us; but it would be worth while to try whether such a substance might not be made by boiling the powder of gypsum dry over the fire, for it will boil in the manner of water; and when this boiling or recalcining was over, the mixing with it resin, or pitch, or both together, with common sulphur, and the powder of sea-shells. If these were all mixed together, and the water added to it hot, and the matter all kept hot upon the fire till the instant of its being used, so that it might be laid on hot, it is possible this secret might be hit upon.

Wax and oil of turpentine may be also tried as additions; these being the common ingredients in such cements as we have accounts of as the firmest. Strong ale-wort is by some directed to be used, instead of water, to make mortar of limestone of a more than ordinary strength. It is possible, that the use of this tenacious liquor to the powdered ingredients of this proposed plaster, might greatly add to their solidity and firmness. Phil. Trans. N^o 93. See STUCCO.

PLASTIC, Πλαστικός, from πλαστικός, of πλατίζω, or πλασσω, *tingo, I fashion, form, &c.* imports as much as *formative*, or a thing endued with a faculty of forming or fashioning a mass of matter after the likenesses of a living being.

Some of the ancient Epicureans, and perhaps the Peripatetics too, imagine a plastic virtue to reside in the earth, or at least to have anciently resided therein; and that it was by means of this, and without any extraordinary intervention of a Creator, that it first put forth plants, &c. Nay, some of them, whether seriously or not we do not undertake to determine, taught that animals, and even man, were the effects of this plastic power.

Some learned modern writers have strenuously contended for the doctrine of a plastic nature, which they have described to be an incorporeal created substance, endued with a vegetative life, but not with sensation or thought, penetrating the whole created universe, being co-extended with it, and, under God, moving matter so as to produce the phenomena, which cannot be solved by mechanical laws; active for ends unknown to itself, not being conscious of its own actions, and yet having an obscure idea of the action to be entered upon. Dr. Cudworth reasons thus: since neither all things are produced fortuitously, or by the unguided mechanism of matter, nor God himself may reasonably be thought to do all things immediately and miraculously, it may well be concluded, that there is a plastic nature under him, which, as an inferior and subordinate instrument, doth drudgingly execute that part of his providence, which consists in the regular motion of matter; yet so as that there is also, besides this, a higher providence to be acknowledged, which, presiding over it, doth often supply the defects of it, and sometimes over-rule it; for as much as this plastic nature cannot act electively, nor with discretion. This doctrine, he says, hath had the suffrage of the best philosophers of all ages. Aristotle, Plato, Empedocles, Heraclitus, Hippocrates, Zeno, and the Stoics, and the latter Platonists and Peripatetics, as well as the chemists and Paracelsians, maintained this doctrine.

“If an unintelligent agent,” says Dr. Price, “can act with such uniformity, and yet so variously, as to produce the order of the world, and govern its motions; if, for instance, it

can frame the bodies of plants and animals, or so direct its own action as to impel the particles of matter towards one another, in such different directions, and with such different forces in different situations, as to be the constant cause of those laws and powers which obtain in the corporeal universe, and on which depend its form and being; if, I say, this is possible, there is an end of all our reasonings about causes and effects, and of all arguments for design and intelligence in the author of nature, taken from its regularity and beauty. It avails nothing to say, that this agent acts in subordination to the deity, and only in virtue of powers given it by him. For it is not supposed to be merely an instrument in the hands of the deity, which never acts except in consequence of being first acted upon; but what it does, it is supposed to do properly by a power inherent in itself, without wanting any *immediate* direction from the deity; and the very reasons that have been assigned for supposing such an agent, are, that it is absurd to think that the deity should be continually employed so much in vain, as is necessary to be supposed, if the general laws of the world are derived from his agency; and that it is dishonouring him to conceive of him as acting himself continually on matter, and immediately concerned in framing the bodies of the meanest plants and insects. To as little purpose is it to say, that omnipotence can give such a power to an unintelligent agent: for what has not wisdom, *cannot* act wisely; and no power can make that to be, which *cannot* be. If the deity can make a cause that acts without knowledge or design to produce regular effects; then it is in the nature of things possible for *such* a cause to produce *such* effects; then design in the cause is not *necessary* to the greatest conceivable order and regularity in the effect, nor can we *certainly* infer the one from the other: then, in short, any thing may produce any thing, and no conclusion with respect to the cause can be drawn, in any case, from what we see in the effect.—The effects of habits have been very improperly alleged, as affording instances of regular action, without knowledge of design. For, what is done by habits, is, I think, always done in consequence of some volition or direction of the mind; and our not being conscious of it is in reality no more than not remembering it, the whole effect of a habit on the executive powers consisting in their more easy and ready compliance with the dictates of the mind. But not to insist on this; let it be granted that regular actions are frequently performed in consequence of habits, without thought or design: this, if true, must be owing to certain powers and laws of the animal economy, which must be accounted for in the same manner with other powers and laws which obtain in nature, and cannot be made an argument for such a blind plastic force as has been contended for, without begging the question. See the truly great and learned Dr. Cudworth's *Intellectual System*, book i. ch. 3, where the opinion on which I have made these remarks is particularly explained and defended. See also an account of a controversy which it occasioned between Mr. Bayle and Le Clerc, in the account of the life and writings of Dr. Cudworth, prefixed to the second edition of the *Intellectual System* by Dr. Birch. Dr. Henry More and Dr. Grew have likewise maintained this opinion." *Intell. System*, vol. i. p. 147, &c. Birch's ed. More's *Imm. of the Soul*, lib. iii. cap. 12. Price's *Diff.*

PLASTICE, Πλαστικη, the plastic art, a branch of sculpture; being the art of forming figures of men, birds, beasts, fishes, plants, &c. in plaster, clay, stucco, or the like.

The workmen concerned in this art are also called *plastiz*, Πλαστικη.

Plastice differs from carving, because here the figures are made by addition of something that is wanting; but in carving, always by subtraction of what is superfluous.

The plastic art is now chiefly used, among us, in fretwork ceilings; but the Italians apply it also to the mantlings of chimnies with great figures.

PLASTRON, in *Ancient Military Armour*, a breast-plate of forged iron occasionally put on, under or between the hauberk and gambeson.

PLASTRON is also a piece of leather stuffed, used by fencing-masters, on which to receive the pushes made at them by their pupils.

PLASWIG, in *Geography*, a town of Prussia, in the province of Ermeland; 28 miles N.W. of Heilsberg.

PLAT, a popular term, among *Mariners*, &c. for a sea-chart.

PLAT, in *Rural Economy*, a term provincially applied to the mould-board of a plough.

PLAT-Veins, in the *Manege*, called in French *ars*, are the veins in which we bleed horses, one in the lower part of each shoulder, when we bleed a horse in the shoulders; and in the flat part of the thighs.

PLATS, in a *Ship*, flat ropes made of rope-yarn, and twisted into *foxes*; they serve to save the cable from galling in the hawse, or to wind about the flukes of the anchors, to save the pennant of the fore-sheet from galling against them.

PLATA, PLATE, in *Commerce*, a Spanish term, signifying silver; as vellon, which they pronounce vellion, signifies copper. These two terms are not only used to express the species of those metals struck in Spain, but also to distinguish between their several monies of account. Plate is reduced to vellon by saying, as 17 is to 32, so is the given plate to the vellon sought; and *vice versa*. See **EXCHANGE**; see also **MARAVEDI** and **REAL**.

PLATA, La, in *Geography*, a vice-royalty belonging to the Spanish dominions in South America, erected in 1778 (not in 1776, as stated under the article **BUENOS AYRES**, from authorities to which we had then access), is one of the most important divisions, and that by which the chief opulence of the Spanish dominion in this part of the world passes to the parent country, and is interwoven with the commerce and interests of Europe. Including the savage Chiquitos and Mojos in the north, and extending to the southern limits of Tuyu and the wide plains called the Pampas, its length from the chain of Vilcanota to the vicinity of the river Negro, may be assumed from 14° S. lat. to near 38°, that is 24°, or 1440 geographical miles. Estalla states the boundary between La Plata and Peru to be now the cordillera of Vilcanota, dividing the province of Carabaya in La Plata from that of Canes and Canches in Peru.

The breadth of La Plata, which is generally pretty equal, may be computed at 12°, or 720 geographical miles. Estalla, cited by Pinkerton, computes the extent at 1000 Spanish or rather American leagues (seeming vaguely to include Chili), and the greatest breadth at 350, forming a triangle of 1000 leagues in height, on a base of 350, equal to 175,000 square leagues; which, as he adds, might support 50,000,000 persons, while in fact there is scarcely one million of civilized inhabitants, and some few savages. Before the establishment of this vice-royalty, the greatest part of the jurisdiction belonged to that of Peru; although the three provinces of Buenos Ayres, Paraguay, and Tucuman, were considered as "Capitanias Generales," that is, the governors had an authority independent of the viceroys of Peru, except in cases of great importance and difficulty.

The

The part of Peru now annexed to La Plata was divided into well-known provinces or districts; and the missions of the Chiquitos, Mojos, and Guaranis, formed three distinct governments. The form of government in this new vice-royalty remained the same, though its title was changed. The ordinance of his Catholic majesty for the sub-division of the vice-royalty was issued in 1782, and appointed nine intendancies. Estalla says that this vice-royalty is divided into nine intendancies, namely Buenos Ayres, comprising the whole of that bishopric; the bishopric of Tucuman embracing two intendancies, that of Salta, and that of Cordova, to which is joined the province of Cuyo-y Mendoza, which, with regard to spirituals, is subject to the bishopric of Chili: in former Peru, there are five intendancies, Potosi, Plata, Puno or Paucarcola, La Paz, and Cochabamba on the S.E. of La Paz; and from the remaining description, which is rather confused, it would appear that Santa Cruz de la Sierra forms the ninth intendancy; but there is also an intendant of Paraguay.

Mr. Pinkerton, for the purpose of a geographical description of this vice-royalty, enumerates the principal provinces, proceeding from the south, which are as follow:

- | | |
|-------------------------|------------------------------|
| 1. Pampas, | 16. Plata, |
| 2. Tuyu, | 17. Santa Cruz de la Sierra, |
| 3. Buenos Ayres, | 18. Chayanta, |
| 4. Cordova, | 19. Oruro and Paria, |
| 5. Cuyo and Mendoza, | 20. Carangas, |
| 6. Charcas, | 21. Pacajes, |
| 7. Guaranis, | 22. La Paz, |
| 8. Paraguay, | 23. Cochabamba, |
| 9. Chaco, | 24. Sicaica, |
| 10. Salta, | 25. Laricaja and Omafuyos, |
| 11. Jujuy, | 26. Chucuito, |
| 12. Chichas and Tarija, | 27. Puno or Paucarcola, |
| 13. Lipes, | 28. Lampa, |
| 14. Atacama, | 29. Afangaro, |
| 15. Potosi or Porco, | 30. Carabaya, which is the |

last province of La Plata on the N. of the great lake of Titicaca, separated from the Peruvian province of Canes and Canches by the grand chain of the cordillera called Vilcanota.

Estalla has briefly described the upper and inferior parts of the vice-royalty, as he calls them. The former part is peculiarly rich in the precious metals, yielding only to Mexico in this respect, and he particularly mentions the cordillera of Lipes; and to Porco belong the celebrated mines of Potosi. The metals of Oruro and Paria are also celebrated. The provinces most rich in gold are Laricaja and Carabaya; while those that produce the greatest quantity of silver are Lampa, Puno, Chucuito, Oruro, Chayanta, and Chicas, not to mention Potosi. Carangas and Pacajes are famous for the breed of pacos, which are used as beasts of burden. Lampa and Afangaro are noted for the produce of wool, the sheep in the former being estimated at near a million. These districts, together with Chucuito, also rear cattle and horses. In the provinces of Salta and Jujuy mules form a prodigious article of trade, supposed to yield 200,000 dollars annually. Cochabamba produces abundance of wheat and maize, so as to supply Oruro, La Paz, and other upland provinces. Santa Cruz de la Sierra, which ranks among the warm regions beneath the chain of mountains, trades in honey, sugar, and beer. In the lower part of the vice-royalty, Estalla observes that the province of Buenos Ayres comprehends three other cities besides the capital, namely, Montevideo, Corrientes, and Santa Fé. The chief products of this province are beeves and mules. For an account of Buenos Ayres, we refer to that article; here

adding some particulars which have come to our knowledge since that article was written. In consequence of the creation of the new vice-royalty, there has been a great increase of commerce and agriculture, and many other advantages have contributed to its progressive prosperity. Formerly its inhabitants had no country-houses, nor any other fruits than a kind of peach; but now every person in easy circumstances has a country cottage and garden, with a variety of fruits, garden plants, and flowers. The houses, though not elevated, are convenient and well furnished. The women are celebrated among the most beautiful in America; and though their dress is less expensive than that of those of Lima, it is more agreeable and elegant. The cathedral has been lately rebuilt; it has three naves, besides several chapels; and in 1798 it had cost half a million of dollars, and the expence of completing it would be as much more. A college is opened, that of San Carlos, which is said to contain 100 students. The ecclesiastical establishment consists of a bishop and some dignitaries; the parish churches are six, and the convents are numerous. Here are two hospitals for orphan children, one of which receives foundlings; and here is also an asylum for women of the town, and in the vicinity are several hermitages and little chapels. The population, which is daily on the increase, is supposed to be about 40,000 persons, of whom the whites or Spaniards compose one half, the other half consisting of negroes, mulattoes, and some few Indians from other parts. Of the Spaniards, some are creoles, born in the country of white parents, and all are chiefly employed in commerce, the arts, and agriculture, while the people of colour are mostly servants. The merchants form the chief part of the population, and of these the greater number is composed of such as are not natives. The inhabitants of Buenos Ayres are, according to Estalla, of a sedate turn, affable and polite. A theatre is established. Bull fights, which were formerly held in the great square, are abolished. Both sexes are handsome, having agreeable countenances, and wearing the Spanish dress. The ladies are fond of music, with which they amuse themselves and their company. Their stockings are fancifully embroidered with gold. The religious processions of this city are numerous and splendid. From Spain, and chiefly from Cadiz, are imported most of the necessaries, as silks, woollens, cotton, linen, hats, &c. They are debarked at Montevideo, and carried in boats to Buenos Ayres, whence they may pass to any part of the vice-royalty, paying 4 per cent. on the sale if carried to the frontier provinces, and 6 per cent. in other cases. The merchants are esteemed men of character and good credit. If Buenos Ayres were not the capital of the province, and at present the great mart of Peruvian commerce, its trade would be inconsiderable, because it has no great branch of native exportation. But the fertility of the neighbouring provinces may in time incline the balance in its favour; and the leather, wool, wheat, tallow, may yield considerable revenues to the vice-royalty. The market of Buenos Ayres is abundantly supplied with all kinds of plants, fruits, meat, bread, fish, fowl, milk, &c. Estalla says, that nearly 1000 head of cattle are slain in the neighbourhood for the daily use of the city: fish is also abundant; but clear water is wanting. The climate is less healthy than that of Montevideo, and the calentures or fevers are pernicious. The city is not deficient in coffee houses, confectionary shops, and taverns; but ice and snow are wanting. The viceroy is lodged in the fortrefs, in which are also the new royal audience, the royal treasury, the chapel, guard-house, and various magazines. The guild-hall is a large building, raised on pillars of brick, where the judges hold the sessions, and underneath

is the gaol. The environs, especially towards Cordova, are pleasant, being full of gardens and groves, diversified with fields of wheat and maize. Cattle are abundant. See BUENOS AYRES. For an account of Montevideo, Santa Fé, Corrientes, Potosí, La Paz, Mendoza, Cordova, Tucuman, Salta, Cuyo, Rioja, the Guaranis, Paraguay, the Pampas, Chucuito, Puno, Oruro, Santa Cruz, Jujuy; see the several articles.

The government of La Plata is entrusted to a viceroy, who has also the title of captain-general, with an assessor, and a fiscal, and also a secretary. The jurisdiction of the viceroy comprehends the whole political management, except the royal treasury, to which his authority does not extend. In the military department he is commander-in-chief under the sovereign. The assessor is also auditor, or supreme judge; and his military jurisdiction is that of captain-general of the veteran troops. The salary of the viceroy is 40,000 dollars; but after certain deductions the residue is about 30,000. He is nominated for three years. The salary of the assessor, fiscal, and secretary, is between 2 and 3000 dollars each. The viceroy is supreme president of the royal audience of Charcas, and also of the new royal audience, erected in 1785, at Buenos Ayres. He exercises the royal vice-patronage, and as such has a grand seat and canopy in the cathedral, where he is treated with the same ceremonies as are paid to the monarch. The royal treasury acknowledges as its chief the intendant of the army; he has a salary of 10,000 dollars; and he audits all the accounts of the vice-royalty. The essential branches of the administration of the royal treasury at Buenos Ayres are the customs, the deposits of tobacco, the monopoly of which has sometimes yielded 100,000 dollars a-year, playing cards and stamped paper, which are of little consequence. Similar duties are exacted in the principal cities of the vice-royalty, and 4 per cent. arises from the sale of merchandize. But the chief branch of the revenue is the duty called *quinto*, though in fact the *tenths* only of all metals. There is also a capitation tax from eight to ten dollars, paid by each person. However, the royal expences are great: the pay of the military, the charges of the sales, and the salaries of the officers of the customs and of tobacco, are prodigious. The intendants of the provinces manage in their jurisdictions the administration of justice, of the police, of the revenues, and of war. In Paraguay, Tucuman, and Santa Cruz, they have joined the command of the troops. The governors intendants have a salary of 6000 dollars, and 600 for the expence of the secretariate and visiting their province. The intendant of Potosí, who is also director of the mint, and of the bank, has a salary of 10,000 dollars. The assessor, appointed by the king to assist these intendants in the administration of justice, has a salary of 1000 dollars, derived from the law-suits, and 500 from the treasury, those of the general intendency excepted, who have 1000.

Besides the nine intendancies there are four governments in the vice-royalty of La Plata, *viz.* that of Montevideo, political and military; and those of the Guaranis, Chiquitos, and Mojos, who have great power military and civil. The establishments on the Patagonian coast, and the Maluinas, or Falkland islands, are subject to particular instructions. Estalla computes the population of this extensive vice-royalty at 1,000,000 Spaniards or creoles, and an inconsiderable number of savages. The population of the other two vice-royalties, *viz.* Peru and New Granada, probably does not exceed 2½ millions. That of Caracas, by the account of Depons, amounts to 728,000, including whites, negroes, and Indians; and Chili

can scarcely exceed the number necessary to complete a million. Brazil, by the best accounts, contains 200,000 whites, and 600,000 negroes, while the natives are little more than sufficient to complete another million. The whole number, therefore, will yield 5½ millions; nor can more, it is thought, than 6 millions be allowed for the general population of the whole of South America.

The internal commerce of this vice-royalty is conducted by means of covered carts or small waggons drawn by oxen, and these form caravans for security against the attacks of the savages. The chief journeys are from Buenos Ayres to Jujuy and Mendoza; beyond which stations it is necessary to have recourse to mules, as the country becomes mountainous. This trade supports many individuals, and increases the circulation of money. The freedom of trade, granted in 1778, contributed very much to augment the general commerce of La Plata; and by a royal ordinance of the 10th of April, 1793, it was permitted, that salted meat and tallow might pass to Spain, or the other colonies, free from duties; a privilege, which had before been granted to the trade in negroes, who were found necessary for the cultivation of the country.

The increase of commerce in this vice-royalty has had a beneficial effect on the agriculture of the country. A royal schedule, in 1791, granted to Spaniards and foreigners the right of introducing negroes, and instruments of agriculture; nor is it improbable, as our author (Estalla) conceives, that this wide and fertile vice-royalty may become, in a few years, not only the granary of the other Spanish colonies, but of the parent country, by the extreme fertility of its soil, and the excellent regulations that are adopted. The climate is singularly benignant, and the extent of fertile lands immense, watered by innumerable rivers and rivulets, which join the majestic waves of the Paraguay and the Parana. The farms, stations, and inclosures for breeding bees, horses, mules, sheep, &c. are already so numerous that they may be counted by millions. Salt rivers and lakes, with numberless creeks, afford convenience for loading boats with salted meat, and the natives are distinguished by their activity and industry. Some districts of the missions produce cotton, lint, and flax; and there are mines of gold at Maldonado and San Luis, 200 leagues from the capital. Although agriculture, fishery, the chase, and the mines serve to enrich these provinces, yet no object is more useful than the breeding of cattle, and we may form some judgment of the number by that of the skins imported. In 1792, 825,609 hides of bees were carried to Spain, besides those sent to the coast of Brazil, and for the purchase of negroes, &c.

The botany of the provinces of this vice-royalty, which formerly belonged to Peru, may be found in the Flora Peruana; and that of the central, southern, and eastern provinces, may be supplied from the work of the industrious Dobrizhoffer, who has, in his first volume, given a general natural history of Paraguay. For a sketch of the botany and zoology, see PARAGUAY.

The mines form a grand object in the new vice-royalty, and are found chiefly in the provinces formerly considered as Peruvian; for, in fact, Charcas, Tucuman, and Buenos Ayres, were all regarded as dependencies of Peru, before the grand change in the year 1778. The upper part of the vice-royalty of La Plata very justly deserves the appellation given to the vice-royalty, as it is the richest country in silver which has yet been discovered on the globe. The mines of gold and silver may be said to be innumerable. All the northern provinces teem with mineral opulence: while Laricaja and Carabaya are distinguished by virgin gold.

gold. (See Porosi.) Besides gold and silver, copper is found at Articoya near Oruro, and in the district of Lipés. A rich mine of tin is wrought in the district of Paria; and mines of lead abound in the province of Chichas.

The following is the state of the mines in the new viceroyalty of Buenos Ayres, as reported by Helms.

Provinces.	Gold.	Silver.	Copper Mines.	Tin.	Lead.

The same author has given the following statement of the whole coinage in Spanish America, from January 1, to December 31, 1790, taken from the official register.

	In Gold. Piafres.	In Silver. Piafres.	Total. Piafres.
At Mexico	628,044	17,435,644	18,063,688
At Lima	821,168	4,341,071	5,162,239
At Potofi	299,846	3,983,176	4,283,022
At Santiago Chili	721,754	146,132	887,886
Total	2,470,812	25,906,023	28,376,855

Pinkerton's Geography, vol. iii. ed. 1807.

PLATA, *La*, a province of the above described viceroyalty. Its capital of the same name was formerly a city of Peru and the see of an archbishop. It was built by captain Pedro Anzures in the year 1539, by order of Gonzalo Pizarro, on the site of Chuquifaca, and called Plata, in allusion to the silver mines of the mountain of Porco in its neighbourhood, from which the Incas obtained great quantities of silver. Its ancient name long prevailed, and, as Ulloa says, is now commonly used. This city stands on a small plain environed by eminences, which defend it from the winds. In summer the temperature of the air is very mild, nor is there any great difference throughout the year; but in winter, which here begins in September and continues till March, tempests of thunder and lightning are very common, and rain is of long continuance. The houses are covered with tile, having one story besides the ground floor; they are roomy and convenient, and have

delightful gardens planted with the fruits of Europe. Water is scarce. The inhabitants consist of Indians and Spaniards, and are said to amount to 14,000. The cathedral is large, of good architecture, and finely adorned with paintings and gildings. The parish is served by two priests, one for the Spaniards, and one for the Indians. Another parish, situated at one end of the city, is appropriated to the Indians living within its precinct, and amounting to about 3000. The convents of the Franciscans, Dominicans, Augustines, the fathers of Mercy, and the college of Jesuits, are spacious buildings, with splendid churches. Here are also two nunneries, and an university dedicated to St. Francis Xavier, the rector of which is always a Jesuit: and also two other colleges, in which lectures of all kinds are read. The magistracy consists of regidores, who are persons of the first distinction, with a corregidor at their head; from these are annually chosen two ordinary alcaldes for superintending the police. Plata was erected into a bishopric in 1551, and in the year 1608 was raised to a metropolis. The jurisdiction of this city includes the imperial town of Potofi, which see. Juan and Ulloa's Voyage, vol. ii. S. lat. 19° 40'. W. long. 66° 46'.

PLATA, *Rio de la*, or river of Silver, a river of South America, which is the conjunct flood of the Paraguay, the Pilcomayo, the Parana, and the Uruguay. The main streams are the Paraguay and the Parana, which see respectively. This river was first discovered by Juan Dias de Salis, in the year 1515, who sailed up the stream as far as an island, which lies in S. lat. 34° 40'. The mouth, nearly 60 leagues broad, is supposed to have been called La Plata from the great quantity of silver found by those who first visited the countries adjacent to its banks; though it was originally called the river Salis, from its first discoverer, who, observing some Indian tents as he sailed up the river, imprudently went on shore with ten men, who were all murdered by the savages. The river Plata, receiving considerable streams, sometimes swells to such a degree, that the banks on each side are overflowed, like those of Egypt by the inundation of the Nile, and thus rendered remarkably fertile. The current of the river, where it falls into the sea, is so rapid, that the water is fresh some leagues distant from its mouth. Its water is also clear, sweet, and wholesome. It abounds with great plenty and variety of fish; and its banks are frequented by a number of very beautiful birds. The distance from the conflux of the Paraguay and Parana to the mouth of the river is near 600 miles, and this interval is interspersed with delightful islands, and navigable by the largest ships. See PARANA.

PLATA, *La*, a small island in the Pacific ocean, near the coast of Peru. S. lat. 1° 10'.

PLATA, *La*, or *Sebastian del Oro*, a town of South America, in the province of Popayan; 60 miles E. of Popayan. N. lat. 2° 50'. E. long. 75°.

PLATA *Keys*, a large sand-bank among the Bahama islands, about 40 miles N. of Hispaniola.

PLATÆ, a word used by some anatomical writers to express the scapulæ.

PLATÆA, in *Ancient Geography*, an island of the Mediterranean, on the coast of Lybia, whither, according to Herodotus, the Cyrenians sent a colony. It was situated on the coast of the Giligames, in the midway between that coast and the isle of Aphrodisias. Scylax places it on the coast of Marmarica.

PLATÆÆ, a town of Greece, in Bœotia. Homer writes this name in the singular Πλατæα, Platæa; but the historians write it Πλατæαι. It was situated on the river Afopus;

Afopus; and seems to have derived its name from Platea, the daughter of an ancient king of the country, who had given his own name to the river Afopus.

The first military exploit of the Platæans, of which we have any knowledge, occurred at Marathon, where they effectually aided the Athenians; they afterwards distinguished themselves on many occasions; but after having experienced the calamities of many wars, and having been frequently driven from their city and recovered it, their ruin was accelerated by Philip, after his victory in the battle of Cheronæa. Near the walls of this city was the tomb of those Platæans who had fallen in combating against the Persians. The other Greeks had also a common sepulchre, whilst the Athenians and Lacedæmonians had another apart for themselves. Jupiter *Liberator* had an altar near the common burying place of the Greeks; both the robes and the statue of the god were of white marble. The Platæans instituted games, which they celebrated every fifth year, on which occasion they ran armed before the altar of Jupiter. The temple of Juno was very splendid and highly ornamented; her statue was of an extraordinary size, and executed by Praxiteles of Pentelician marble. Minerva had also a temple at Plataea, which had been erected of the spoils gained from the Persians in the battle of Marathon. Her statue was the work of Phidias, and was not less in size, than that of bronze in the citadel at Athens. In this city was also the tomb of Leitus, who was the only Bœotian chief who returned from the siege of Troy.

PLATALEA, the *Spoon-bill*, in *Ornithology*, a genus of birds of the order Grallæ. The generic character is this: the bill is long and thin; the tip dilated, orbicular, flat; the nostrils are small, and at the base of the bill; tongue short, pointed; the feet are four-toed and semi-palmate. There are three

Species.

* **LEUCORODIA**; White Spoon-bill. Body white; chin black; hind-head sub-crested. The bill is black, brown, or spotted; tongue heart-shaped; irids grey; lores, orbits, and naked dilatable chin black; quill-feathers sometimes tipped with black; the legs are black. There are two varieties of this species, of which the *first* has the wings varied with black and white, the legs yellowish; in the *second* the body is all white; legs flesh-colour. The white or common spoon-bill weighs about three pounds and a half, and measures two feet eight inches in length. It inhabits from the Feroe islands to the Cape of Good Hope; it is rarely seen in England, but its appearance is sufficiently frequent to justify us in placing before it the asterisk. It lives on grass, carices, the roots of reeds, serpents, frogs, muscles, and other shell fish; but especially on fishes, which it often seizes from other birds. It makes its nests in high trees, near to the sea, and lays three or four white eggs, speckled with pale red spots. The flesh of the young spoon-bill is reckoned very good, little inferior to that of the goose.

AJAJA; Roseate Spoon-bill. Body rose coloured; tail-coverts scarlet. There is a variety blood-red; neck white; collar black; tail-feathers scarlet. It inhabits South America, and is twenty-seven inches long.

PYGMEA; Dwarf Spoon-bill. Body above brown, beneath white. It is only the size of a full-grown sparrow, and is found in Guiana and Surinam.

PLATAMON, a word used to express a low and smooth rock, just appearing above water.

PLATAMONÉ, in *Geography*, a town of European Turkey, in Macedonia, at the mouth of the river Jenicoro; 44 miles S.S.E. of Edessa.

PLATANAL, a small island in the Spanish main, near the coast of Darien. N. lat. 9° 6'. W. long. 80° 40'.

PLATANARIA, in *Botany*, a name by which some authors have called the *spargarium*, or burr-reed, from its round echinated fruit, which in shape and size much resemble those of the platanus.

PLATANI, in *Geography*, a river of Sicily, which rises near Castro Nuovo, and runs into the sea, 10 miles S. of Sacca.

PLATANUS, in *Ancient Geography*, a town of Asia, in Syria; situated on the western bank of the river Orontes, E. of mount Casius, towards N. lat. 35° 50'.—Also, a town of Phœnicia, placed by M. d'Anville between Berytus and Sidon, in the vicinity of Libanus.

PLATANUS, in *Botany*, the classical name of the Plane-tree, adopted by the Romans from the Greeks, whose $\pi\lambda\alpha\tau\alpha\upsilon\sigma$ was derived from $\pi\lambda\alpha\tau\upsilon\varsigma$, *broad*, in allusion to the wide spreading branches, and umbrageous foliage, of this noble and favourite tree.—Linn. Gen. 498. Schreb. 649. Willd. Sp. Pl. v. 4. 473. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 5. 304. Pursh North Amer. v. 2. 635. Juss. 410. Lamarck Illustr. t. 783. Gært. t. 90.—Class and order, *Monoclea Polyandria*. Nat. Ord. *Amentacea*, Linn. Juss.

Gen. Ch. Male flowers compound, disposed in a globular catkin. *Cal.* A few slight minute segments. *Cor.* scarcely discernible. *Stam.* Filaments oblong, swelling upwards, coloured; anthers square, surrounding the lower part of the filament.

Female flowers numerous, forming a globe, on the same tree. *Cal.* of several minute scales. *Cor.* Petals several, concave, oblong, club-shaped. *Pist.* Germens several, awl-shaped, ending in awl-shaped styles; stigma simple, recurved. *Peric.* none; several fruits are collected together into a globe. *Seed* roundish, tapering at the base, crowned with the awl-shaped permanent style, the bottom of the seed being surrounded with copious capillary down.

Obf. Linnaeus submits his description of the flowers to the more attentive scrutiny of "some lynx-eyed observer," but no one as yet has taken up the challenge. Mr. Bauer's fine drawing of *P. orientalis*, for the Flora Græca, has no male flowers.

Eff. Ch. Male, Catkin globose. Calyx and corolla obsolete. Anthers surrounding the filament.

Female, Catkin globose. Calyx of many leaves. Corolla none. Stigma recurved. Seed club-shaped, pointed by the style, brittle at the base.

1. *P. orientalis*. Oriental Plane Tree. Linn. Sp. Pl. 1417. Willd. n. 1. Ait. n. 1. (*Platanus*; Ger. Em. 1489. Matth. Valgr. v. 1. 120. *P. orientalis verus*; Duham. Arb. v. 2. 172. t. 33.)—Leaves palmate, five-lobed; wedge-shaped at the base; segments lanceolate, sinuated; ribs pedate. Stipulas nearly entire.—Native of the Levant.—A specimen in the Linnean herbarium was gathered by Hasselquist, from a remarkably large tree, in the island of Cos, now Stanchio, the circumference of whose trunk was thirteen and a half Swedish ells, about eight yards and a half. This beautiful species is among the earliest exotic trees recorded to have been cultivated in Britain, being mentioned by Turner in 1548; but the great lord Bacon appears to have been the first who planted it in any abundance. The Greeks and Romans esteemed this tree very highly for its shade, as well as beauty. About the Roman villas it was always planted, and sometimes honoured, rather than benefited perhaps, with libations of wine. Some ancient trees of this kind are reported to have attained a more ample size than the above.

PLATANUS.

above. The finest Oriental Plane, we believe, in England, stands at one corner of Chelsea garden, raising its round head far above all neighbouring objects. Miller speaks of this as the Maple-leaved variety, now made a species, see n. 3; and he asserts, that young plants, which sprung from its seeds, proved of the common sort. We have no opportunity at present of investigating this point. An elegant specimen of the Oriental Plane, whose spreading branches are feathered down to the ground, stands near the temple in the arboretum at Kew. In Germany, this species is not hardy enough to attain the size of a tree. The *branches* of *P. orientalis* are round, smooth, slightly zigzag. *Leaves* deciduous, alternate, on longish, round, downy stalks, rather deeply palmate, about a span wide, with five lanceolate, more or less deeply or copiously sinuated, lobes, whose points are callous or glandular, and somewhat incurved: both sides are smooth, with pedate ribs, and innumerable fine veins: in an early state only, the leaves are clothed with mealy deciduous down. *Stipulas* tubular, surrounding the branch, with a spreading border, more entire in this species than the rest. *Buds*, as in the whole genus, enclosed in the hollow base of each *footstalk*, ovate, obtuse, compressed, quite concealed till the leaves fall. By their swelling, the buds promote the separation of the *footstalks*. *Flowers* in three or four globular heads on each long drooping stalk, appearing in April and May. *Stigmas* crimson. Each globe of ripe *fruit* is an inch or more in diameter.

2. *P. cuneata*. Wave-leaved Plane Tree. Willd. n. 2. Ait. n. 2. (*P. orientalis undulata*; Ait. Hort. Kew. ed. 1. v. 3. 364.)—Leaves three or five-lobed, toothed, wedge-shaped and elongated at the base; triple-ribbed, nearly smooth.—Gathered by Hasselquist in the Levant. Miller is said to have cultivated it in 1739. In some points this answers to his “Spanish, or Middle Plane Tree;” but we find great difficulty in applying with certainty the English names of this genus, which are in use amongst nursery-men. The *leaves* in our wild specimen are remarkably wedge-shaped, and elongated at their base; in consequence of which there are only three principal ribs, of which the lateral ones are seldom precisely opposite: the lobes are three, strongly sinuated, but not separated so far as the middle of the leaf. *Footstalks* long. Miller describes them short, and covered with short down, in his Spanish Plane, which character answers to another specimen in the Linnæan herbarium from Burgundy, resembling the true *orientalis*, except in its short *footstalks*, and strongly toothed *stipulas*. This specimen may be a nondescript species. The leaf in Duham. Arb. v. 2. t. 34. given for the following, represents our plant very well.

3. *P. acerifolia*. Maple-leaved Plane Tree. Willd. n. 3. Ait. n. 3. (*P. orientalis aceris folio*; Tourn. Cor. 41.)—Leaves heart-shaped, five-lobed, smooth, distantly toothed; abrupt and three-ribbed at the base.—Native of the Levant, where it was noticed by Tournefort. The Hort. Kew. mentions this species as cultivated here before 1724. Willdenow says it is hardy, forming a lofty tree, in Germany, and that it is known from all the rest by the *leaves* being abrupt, not wedge-shaped at the base, and having their two lateral ribs spring from the top of the *footstalk*, unaccompanied by any leafy expansion beyond them. He adds, that they are extremely like those of the Sugar Maple, *Acer saccharinum*. We have no specimen that answers to this description, nor does Duhamel’s t. 34. given as Tournefort’s plant, agree with Willdenow’s account.

4. *P. occidentalis*. American Plane Tree. Linn. Sp. Pl. 1418. Willd. n. 4. Ait. n. 4. Cateb. Carolin.

v. 1. 56. t. 56. Duham. Arb. v. 2. 172. t. 35.—Leaves with five angles, slightly lobed, toothed; wedge-shaped at the base; downy beneath.—Native of the banks of rivers in North America, from Canada to Florida, as well as in Louisiana. Mr. Pursh says this is perhaps the largest North American tree, some individuals, on the fertile banks of the Ohio and Mississippi, measuring from ten to sixteen feet in diameter. It is known by the names of Buttonwood, Water Beech, Sycamore, and Plane Tree; in Canada by that of Cotton Tree. This Plane has been cultivated in England about 180 years, and is usually hardy with us, as well as in Germany, flowering like the other species in April and May; but the winter of 1810, or spring of 1811, was fatal or injurious to most of the Occidental Planes in England, owing perhaps to transient cold, not generally observed, at some critical period of the growth of these trees in particular. The broad, slightly lobed foliage distinguishes this species readily from all the rest. The three or five principal ribs have a considerable leafy, though scarcely wedge-shaped, expansion below the point of their union. The *stipulas* are wavy, with blunt shallow teeth. *Footstalks* rather short, downy.

PLATANUS, in Gardening, contains plants of the exotic deciduous tree kind, of which the species cultivated are; the oriental plane tree (*P. orientalis*); and the American plane tree (*P. occidentalis*).

Of the first sort there are two varieties, as the *maple-leaved*, which has not its leaves so deeply cut as those of the eastern plane: they are divided into five segments, pretty deep, but are not lobed, like those of the occidental plane. The petioles are much longer than in either of the species, and the upper surface of the leaves is rougher, so that they might be taken for different sorts, if it was not known that they rose from the same seeds.

The *Spanish* plane, which has larger leaves than either of the sorts, and are more divided than those of the occidental, but not so much as those of the oriental. Some of the leaves are cut into five, and others into three lobes only; these are sharply indented on the edges, and are of a light green; the *footstalks* are short, and covered with a short down. This is by some called the middle plane tree, from the leaves being of a shape between the two species.

Method of Culture.—These plants may be increased by seed, layers, and cuttings; but principally in the two last methods.

The best season for sowing the seed is autumn, if they can be procured, otherwise in the spring, upon a somewhat lightish mellow soil: the ground having been dug and raked, it should be formed into four-feet wide beds, and the seeds then scattered evenly on the surface, and raked in, or with the back of a rake the earth be previously trimmed off the surface near half an inch deep into the alleys; then sowing the seed, and directly with the rake turned the proper way, drawing the earth evenly over the seeds, and trimming the surface smooth, when many of the plants will rise in spring, but probably not generally till the spring following. When they are one or two years old, they should be planted out in nursery-rows, two feet asunder, and about half that distance in the lines; to remain till of a proper size for being finally set out.

In the layer method, some stout plants must be planted for stools, which in a year after must be headed down near the bottom, that they may throw out many shoots near the ground convenient for laying; which, in the autumn after they are produced, should be laid down by slit-laying; and by the autumn after they will be well rooted, and form plants

plants two or three feet high, which may be separated, and planted in nursery rows, as the seedlings. They succeed very readily in this way.

Most of the sorts take tolerably by cuttings of the strong young shoots; but the latter more freely than the former kinds. The most proper season for planting them is the autumn, as soon as the leaf falls, or occasionally in the spring; choosing a moist soil for the purpose, when many of the cuttings will grow, and make tolerable plants by the autumn following.

These last two methods are the only ones in order to continue the distinct varieties effectually.

These trees have a very ornamental effect in all sorts of plantations, from their large growth and the great size of their leaves.

PLAT-BAND, a border or bed of flowers, along a wall, or the side of a parterre; frequently edged with box, &c.

PLAT-BAND, in *Architecture*, is any flat square moulding, whose height much exceeds its projecture.

Such are the faces, or fasciæ, of an architrave, and the plat-bands of the modillions of a cornich.

The plat-band is signified in Vitruvius, and others, by the words *fascia*, *tania*, and *coria*.

PLAT-BAND of a door or window, is used for the lintel, where that is made square, or not much arched.

These plat-bands are usually crossed with bars of iron when they have a great bearing; but it is much better to ease them by arches of discharge built over them.

PLAT-BANDS of flutings, the lists, or fillets, between the flutings of columns.

PLATE, in *Commerce*, denotes gold or silver wrought into vessels for domestic uses.

PLATE, in *Geography*, a town of Hinder Pomerania, on the Reg; 22 miles S. of Colberg. N. lat. 53° 49'. E. long. 15° 17'.

PLATE, in *Heraldry*, is a round flat piece of silver, without any impression; but, as it were, formed ready to receive it.

The term is used only by the English heralds. In other nations they are known by the name of *besants argent*.

PLATE-Mail, in *Ancient Armour*. See **MAIL**.

PLATE-Armour, formed of small round plates of iron, like the scales of a fish, was known and used among the ancients. There are many specimens of Roman plate armour in the museums of curious collectors. If the suit of armour, shewn in the Tower of London, be really what it is said to have been, the armour of John de Courcy, earl of Ulster, in Ireland, brought with him to the Tower; it will prove that plate-armour was in use as early as 1204, the date of his confinement. The general prevalence of it was checked by the large sum which a complete suit of plate-armour cost. It was, however, introduced both here and in France into more common use about the middle of the 14th century.

PLATE, a term used by our *Sportsmen*, to express the reward given to the best horse at our races.

The winning of a plate is not the work of a few days to the owner of the horse, but great care and preparation are to be made for it, if there is any great dependence on the success. A month is the least time that can be allowed to draw the horse's body clear, and to refine his wind to that degree of perfection that is attainable by art.

It is first necessary to take an exact view of his body, whether he be low or high in flesh; and it is also necessary to consider whether he be dull and heavy, or brisk and active when abroad. If he appear dull and heavy, and there is reason to suppose it is owing to too hard riding; or, as the proverb expresses it, to some greafe that has been dissolved

in hunting, and has not been removed by scouring, then the proper remedy is half an ounce of diapente, given in a pint of good sack; this will at once remove the cause, and revive the creature's spirits. After this, for the first week of the month, he is to be fed with oats, bread, and split beans, giving him sometimes the one, and sometimes the other, as he likes best; and always leaving some in the locker, that he may feed at leisure when he is left alone. When the groom returns at the feeding time, whatever is left of this must be removed, and fresh given; by this means the creature will soon become high spirited, wanton, and full of play. Every day he must be rode out an airing, and every day it will be proper to give him a little more exercise; but not in such a degree as to make him sweat too much.

The beans and oats in this case are to be put into a bag, and beaten till the hulls are all off, and then winnowed clean; and the bread, instead of being chipped in the common way, is to have the crust clean cut off.

If the horse be in good flesh and spirits when taken up for its month's preparation, the diapente must be omitted; and the chief business will be to give him good food, and so much exercise as will keep him in wind, without over-sweating or tiring his spirits. When he takes larger exercise afterwards, towards the end of the month, it will be proper to have some horses in the place to run against him. This will put him upon his mettle, and the beating them will give him spirits.

This, however, is to be cautiously observed, that he has not a bloody heat given him for ten days or a fortnight before the plate is to be run for; and that the last heat that is given him the day before the race, must be in his clothes: this will make him run with greatly more vigour when stripped for the race, and feeling the cold wind on every part. In the second week, the horse should have the same food and more exercise: and in the last fortnight he must have dried oats, that have been hulled by beating; after this they are to be wetted in a quantity of whites of eggs, beaten up, and then laid out in the sun to dry; and when as dry as before, the horse is to have them. This sort of food is very light of digestion, and very good for the creature's wind. The beans in this time should be given more sparingly, and the bread should be made of three parts wheat, and one part beans. If he should become costive under this course, he must then have some ale and whites of eggs beaten together: this will cool him, and keep his body moist.

In the last week the mash is to be omitted, and barley-water given him in its place; and every day, till the day before the race, he should have his fill of hay; then he must have it given him more sparingly, that he may have time to digest it; and in the morning of the race day, he must have a toast or two of white bread, soaked in sack, and the same just before he is led out of the field. This is an excellent method, because the two extremes of fullness and fasting are at this time to be equally avoided; the one hurting his wind, and the other occasioning a faintness that may make him loose. After he has had his food, the litter is to be shook up, and the stable kept quiet, that he may be disturbed by nothing till he is taken out to run. See **RACING**.

PLATES, in *Gunnery*. The *prize-plates*, are two plates of iron on the checks of a gun-carriage, from the cap-square to the centre, through which the prize-bolts go, and on which the hand-spike rests, when it poises up to the breech of the piece. *Breach-plates* are the two plates on the face of the carriage, one on each check. *Train-plates* are the two plates on the checks at the train of the carriage. *Dulidge-plates* are the fixed plates on the wheel of a gun-carriage, where

where the fellows are joined together, and serve to strengthen the dulidges.

PLATES, *Copper*, in *Engraving*. See COPPER-Plates.

PLATES, *Ground*, in *Building*. See GROUND-Plates.

PLATES, *Pintle*. See PINTLE.

PLATE-Glafs. See GLASS.

PLATES, *Colours of Glafs*. See COLOURS.

PLATE-Knees, in *Ship Building*, are iron knees, made of flat bars of iron, about one inch thick, and four inches broad; the arms are bolted through the end of the beam, and a chock of oak under the beam, which is first bolted through the ship's side. This method of connecting the beams to the side is an excellent substitute for wood hanging-knees.

PLATE-Longe, in the *Manege*, a woven strap, four fathoms long, three fingers broad, and as thick as one. It is used for raising a horse's legs, and sometimes for taking him down, in order to facilitate several operations of the farrier. Some improperly give the name of plate-longe to the martingale.

PLATEA, in *Ornithology*, the name of a bird of the long-necked kind, approaching to the nature of the stork and heron, and called in English the spoon-bill. See PLATALEA.

PLATED MANUFACTURE, in the *Arts*. From the valuable properties possessed by silver as a metal, it is much to be regretted that it is not sufficiently plentiful, so as to be used for the fabrication of such articles as are liable to corrosion; more especially such utensils as are employed for culinary purposes. This desirable object has given rise to the desideratum of covering some of the cheaper metals with silver, and this art has always been known by the name of plating.

The art of plating with silver appears to have been first applied to articles made of brass, after they were in other respects finished. It is known by the name of French plating, and was formerly much used for brass candlesticks. After the goods were polished, and perfectly free from grease, and indeed any other extraneous matter, the part to be plated was heated to a temperature something short of changing the colour of the metal. Leaf silver was now laid upon the part, and, while hot, was rubbed on with a hardened steel burnisher, perfectly dry and clean. By this means the silver adhered firmly to the brass, which, from the action of the burnisher, assumed a fine polish. These had much the appearance in colour and lustre of those of the present day. They possessed but little permanence, owing to the thinness of the covering. This art is scarcely now practised, from the introduction of the superior plan of plating upon ingots of copper, and forming the utensils out of the sheets and wire made from the ingots. This latter is at present carried on to an immense extent in Sheffield, and also at Birmingham, but on a lesser scale.

The inventor of this method of making plated articles was not aware of its great importance. He began by making it into snuff-boxes, and other trifling articles. It afterwards was extended to the manufactory of pints and tankards, and other articles, by a Mr. Hancock, who erected a mill near Sheffield for rolling the ingots. This mill is at present employed for this purpose by the son of the above gentleman.

The plated manufacture is divided into three departments, in each of which a distinct set of workmen is employed.

Those workmen employed in making vessels, such as are required to be raised by the hammer, are called braziers, probably from braziers being first employed in it.

The next are called candlestick-makers, being exclusively employed in making all the varieties of these articles.

The next and last are called pierce-workers: these were originally employed in making articles with ornamental open work, such as bread-baskets, and trays of different kinds.

This open work was formed by piercing the substance with punches of different shapes, by means of a screw-press called a fly.

This species of work is now become obsolete, since the invention of plated wire. The articles in which pierce-work had been made, are now formed by the varied interfections of wires, which give great lightness and elegance, with less waste and more expedition. The workmen employed in this department are still called pierce-workers.

Previously to describing particularly the different branches of this art, we shall give the method of preparing the plated sheets and wire of which all the different articles are made.

The ingots on which the silver is laid are not pure copper, but an alloy, consisting of copper and brass; this gives it a degree of stiffness greater than that of copper, which renders it less liable to be deformed when in use.

Fig. 12. in *Pl. Plated Manufacture*, represents a section of the furnace used for melting the alloy for the purpose of casting. The crucibles are those made at Chelsea with black-lead. The ingot-moulds are of cast-iron, consisting of two pieces, fastened together by two rings, with wedges, the interior being of the shape of a parallelepipedon, about three inches broad, 14 in thickness, and about eighteen or twenty long. The mouth-piece, into which the metal is poured, makes an angle with the length of the cavity; so that when the mould is placed on the ground, with the narrow side uppermost, and makes an angle with the horizon of about ten degrees, the mouth-piece points directly upwards. The inclination of the mould and the length of the mouth-piece are to give a certain head of liquid metal, which determines the impurities of less specific gravity than the metal to rise into the cavity of the mouth-piece, in order to insure the soundness of the ingot. If this were not attended to, the sheets rolled from such ingots would abound with seams and loose places. It is easy to see that a small hole in the ingot would be the source of a seam by extension, and a larger cavity would have the effect of making hollow places in the substance of the sheet, which frequently peel off with the silver after plating.

The proper heat of the metals, and the temperature of the mould when the metal is poured, are of great importance, as far as regards the soundness of the ingot. When the metal is too cold, and its liquidity of course imperfect, the impurities cannot freely ascend, which causes imperfection in its substance. The same effect may take place from the moulds being cold: this, with the great conducting power of the metal mould, rapidly robs the metal of its caloric, and lessens its liquidity. The proper heat for the moulds is something short of burning the fat with which they are greased on the interior surface. The presence of fat which contains hydrogen has a happy effect in preventing the surface being rough. Its presence is therefore essential, and hence the moulds should never be so hot as to destroy it. On the other hand, the metal should not be too hot, as in this case it remains longer in the liquid state than is proper: this has the effect of allowing the metal to assume a more complete crystalline arrangement than under ordinary circumstances. When an ingot under such circumstances is broken, the crystals are very distinct. The sheet rolled from an ingot so cast, will be found to exhibit on its surface very thin loose pieces, which peel off. This is frequently a source of great mischief to the manufacturer. After the pieces are plated

and

PLATED MANUFACTURE.

and rolled, this last inconvenience is frequently so great, as to render the whole sheet useless, except to work over again.

It will be remembered, from what we observed respecting the temperature of the ingot moulds, that the proper heat for the metal can only be acquired by practice. Men of some talent and observation should have the management of casting and plating. It is notorious, however, throughout the trade, that the men employed in this essential department are generally taken from the class of common labourers.

The best test for the proper degree of heat of the metal is its colour, and the appearance of liquidity. When it first fuses it appears stiff, and of the colour of the red cokes of the furnace: with a greater heat it becomes more liquid, and assumes a blueish colour. This latter is the proper state for pouring it into the mould. If the heat be greater, the zinc of the brads, and perhaps the copper itself, begins to burn. This arises from the metal's assuming the form of vapour, which combines with the oxygen of the atmosphere. When the metal has become solid in the mould, the wedges which keep the two halves of the mould together are slackened, to prevent the ingot from breaking, by its contraction, during cooling. When it is taken from the mould its surface ought to be smooth and metallic. Its fracture should exhibit a rough uniform crystallization, in which the crystals present small surfaces. If the crystals appear distinct, with large faces, the metal will be shelly when rolled.

For the ordinary kind of work these ingots are generally cut in two in the middle, being more convenient for plating than longer pieces.

The next process is to dress the face of the ingot for the purpose of receiving the silver, on one or both sides, as it may be intended to be single or double plated. This is effected by filing, which is continued till the surface becomes entirely free from the least blemish. This is so important, that the naked eye should not be depended upon. A very small hole in the ingot would become a surface on rolling, and the silver would come off in that part. The surface of the copper should, therefore, be minutely examined by a magnifier before the silver is laid on. The thickness of the silver to be laid on the copper will be best known, when it is understood, that the silver, in single plated metal, or that plated on one side only, is from 8 to 10 pennyweights to the pound troy of copper; and, of course, double that quantity when plated on both sides. If the ingot of copper be $1\frac{1}{4}$ thick, the silver plate to be laid upon it, at eight pennyweights to the pound, will be $\frac{1}{2}$ of an inch, and a square inch of it will weigh about 90 grains. When the plate of silver is cut to a little less than the size of the copper surface, made flat, and scraped perfectly clean, the copper surface being equally clean, they are laid together, and the silver plate is tied down with wire. A little of a saturated solution of borax is now insinuated under the edge of the silver plate on every side: this fuses at a low red heat, and prevents the oxygen of the atmosphere from affecting the surface of the copper, which would prevent the adherence of the silver. In this state the ingot is brought to the plating furnace.

In *fig. 12.* B is an iron door, with a small hole to look through. This furnace has a grate on a level with the bottom of the door. The fuel consists of cokes. The ingot is laid upon the bare cokes, and the door shut. When it has acquired nearly a proper degree of heat, the plater applies to the hole in the door to observe the proper point, when the process is finished. When the silver and copper are uniting, the surface of the former begins to be

riveted, and this is the sign to remove the ingot from the fire as quick as possible. If it were allowed to stop longer, the silver would become alloyed with the copper, and completely spoiled.

In this process, the silver is, in fact, foldered to the copper, although no folder is expressly employed. It is well known to chemists, that an alloy of silver and copper, as well as many other alloys, is more fusible than either of the simple metals. From what takes place in the above process, it will be easily inferred, that a portion of silver and copper unite at contiguous surfaces, which fusing before the silver or the copper, unite the silver with the copper. The ingot, being now plated, is made perfectly clean, and is ready to be rolled. The first rollers employed for plated metal are of cast-iron, similar in size and construction to those employed for sheet iron and sheet copper. (See ROLLING MILL.) The metal is rolled cold, and annealed from time to time. When it has gone through the rollers a certain number of times, it acquires a certain degree of hardness, so that the rollers have not much effect upon it; and if the rolling were continued, the metal would crack. To remedy this evil, the metal is taken to a reverberatory furnace. It is laid upon a hearth of brick or fire-stone, and the flame of coal made to pass over it. The heat, however, is not intense, since the metal is required to be slowly heated to a dull red. It may now be cooled in the quickest way possible to save time, as quenching in water does not affect it, as is the case with steel. It now passes through the rollers, as before, till it becomes hard, and then annealed and rolled again, till it is reduced something short of the size required. This being done, it is again annealed and passed through a pair of rollers faced with cast steel, and finely polished. This gives the surface great smoothness and truth. It is now annealed for the last time: after this, the sheets are immersed in hot dilute sulphuric acid, then scowered with fine Calais sand, which fits them for the workmen to shape into different articles.

Having described the method of preparing the sheet plated metal, we shall next give an account of the method employed for manufacturing plated wire. This is generally a distinct business, being unconnected with the business of making the plated goods.

The pieces of metal to be plated for the purpose of making wire, are forged out of bar copper unalloyed. These pieces are of a cylindrical shape, and about 18 or 20 inches long, and about $1\frac{1}{2}$ inch in diameter. The true cylindrical shape is given to the copper by wire-drawing: it is then made perfectly clean and metallic by scraping. The silver to be laid upon it is much thinner in proportion to the copper than was stated in the sheet metal. The silver is first formed into a tube, one edge projecting a little over the other. A copper cylinder, a little less in diameter than the tube, and so much longer as to admit one end of it being fastened into a hole, is now heated red-hot, and fastened by one end in the hole. The tube is now slipped upon it, with the seam upwards. A flat steel burnisher, with rounded polished edges, and a handle at each end, is now rubbed briskly backward and forward upon the overlapped edges of silver, at the same time using considerable pressure. By this means the two surfaces are completely welded together, so that it would be difficult to find where the union had taken place.

The cylinder of copper intended to be plated, is now made perfectly clean, the inside of the silver tube being the same. It is now put upon the cylinder, which is about
two

two inches longer than the tube; a small groove is made round the cylinder coinciding with the ends of the silver tube. Into this groove the ends of the tube are closely worked, so as to render the space between the tube and the cylinder perfectly air-tight. The necessity of this will be obvious, since the whole is required to be heated red-hot, which would cause the oxydation of the copper, and prevent the silver from adhering to it. When the cylinder and tube are together heated slightly red-hot, the same burnisher that was used to unite the tube is now rubbed briskly over the tube in a longitudinal direction. This unites the silver firmly to the copper, and makes it fit for drawing into wire of various forms and sizes. The machinery employed for drawing this wire is precisely similar to that employed for brass and copper wire. The great variety of figure and form given to it depends upon the plate through which it is drawn. Some are flat, others half round, some fluted, or with mouldings. It is chiefly used for making bread-baskets, toast-racks, snuffers, and many other articles, affording much neatness and elegance, with little manual labour. The wire after drawing, like sheets after rolling, is annealed, and afterwards cleaned with hot dilute sulphuric acid.

We shall first describe the manufacture of sheet metal into various articles. It may be easily conceived, that the nature of this metal is so similar to copper, that the working of it with the hammer into various forms will be very similar to that used by copper-smiths, with the difference of more exact and complete tools, and greater care on account of the value of the metal. Formerly all the different shaped vessels were made with the hammer, which made the price of labour very great. Now, all vessels of simple form, and not of large size, are formed in dies by means of the stamping hammer. This operation is now so general, that some manufacturers employ as many as six or eight of these engines.

Figs. 1 and 2 are two views of the stamp. *A* is a large stone, the larger the better; *b*, the anvil on which the die, *c*, is secured by four screws. See ground plan.

In *fig. 1*, *a, a*, are two upright square pillars, with the angles opposed to each other, which work in angular recesses in the hammer *d*. This admits the hammer to slide freely and truly from top to bottom, by pulling at the rope *f*, which passes over the pulley *e*. This hammer is let fall from different heights, according to the effect to be produced.

All vessels may be raised by the stamp, with the exception of such as are immoderately large, or those of inordinate depth, compared with the diameter. Vessels which are of less diameter at the top and bottom than in the middle, must either be stamped on two pieces, or raised with the hammer by hand.

The dies are, or ought to be, made of cast steel, but it should be as hard as to weld to iron, so that the iron should not be much below the surface of the die. This precaution is necessary only when the die requires to be hardened. In other respects the whole may be cast steel. Those unhardened should be of harder cast steel. No other steel can answer, as it would be liable to abound with flaws, and would not be uniformly hard.

When the die is placed upon the anvil, and the metal cut into pieces of proper size, the next thing is to surround the top of the die with a paste made with oil and clay, an inch or two above the surface. This cavity is now filled with melted lead. The under side of the stamping hammer has a flat face of iron fitted into it, about the breadth and length of the die; this is called the *lickerup*. When the

lead becomes solid, the hammer is raised to a certain height and let fall upon it. The under side of the *lickerup*, from being cut on the surface into teeth in shape like those of a rasp, firmly adheres to the lead, which afterwards rises with the hammer. The metal is now placed over the die, and the hammer with its lead made to fall upon it, till the impression on the metal is complete. If the vessel to be stamped be of any considerable depth, two or three dies are often used, one bigger than another, the last being of the proper size and shape. It sometimes happens, that when the vessel has a long conical neck, they are obliged to have recourse to an auxiliary operation called drafting. These in the plate are called embossing punches.

In *fig. 11*, the punches are made of cast steel, and the cavities turned out in a lathe. The pieces *a, b*, are of lead. This operation is performed by a series of these punches of different sizes, beginning with the largest first, and gradually going on to the smallest. By this means a hollow cone may be raised out of a flat plate, three or four inches in length, and not more than an inch in diameter at the widest part. These punches are also employed for small articles of too great delicacy for the stamp.

It frequently happens, that one part of an article is made by the stamp, and the rest by the hammer. Sometimes they are rudely formed by the hammer and finished by the die.

Cylindrical and conical vessels are mostly formed by bending and foldering. The bending is performed on blocks of wood with wooden hammers, to avoid injuring the plated surface. We shall here recommend a method of turning rings, or any thing in a cylindrical or conical shape. It is already used to great advantage by tin-plate workers. This is done by a machine consisting of three rollers, a section of which is shewn in *figs. 5 and 6*. *A, B, C*, are the three rollers, and *abcd* the piece of metal passed through them to receive the cylindrical or conical shape.

The upper roller, *A*, can be raised or lowered at pleasure, which has the effect of determining the diameter of the cylinder. When one end of the upper roller is higher than the other, it gives the conical shape. In order to solder the cylinder or cone, the two edges are made very true, and are kept in contact by binding with small iron wire. The part where the folder is intended to be run must be made perfectly clean by scraping. The folder employed is that called silver folder. It is an alloy of brass and silver, or rather an alloy of silver, zinc, and copper. The alloy of copper and silver is more fusible than either of these metals, and may be employed as a folder for silver, copper, or plated metal, when the plated metal has no zinc in its composition. It is, however, necessary to employ an alloy of brass and silver as a folder for plated metal. The brass should be the least possible, being no more than what is necessary to give the requisite fusibility to the folder, since too much brass would not only injure the colour, but its malleability is impaired, and the seam would break when it came to be hammered.

The solder is first cast into an ingot, and then rolled thin enough to cut with shears into small shreds. Besides the folder they also employ borax, and a substance which floats on the top of melted glass, and is taken off as refuse. It is called *sandiver*, and probably consists of sulphat of potash and flint. The borax is first calcined, which consists in driving off the water of crystallization. The white powder is then mixed with a little water, a small quantity of the powdered *sandiver* being at the same time added. After the seam to be foldered has been smeared with this pulpy mass, and the bits of folder laid on, the whole is exposed to the heat of a lamp with a blowpipe; or if the substance be large, to a charcoal fire, urged with bellows. The borax first

PLATED MANUFACTURE.

fuses, and defends the parts to be united from the action of the air. The heat is then increased rapidly till the folder melts. The use of the sandiver is to prevent the iron wire from being foldered to the other metal. It appears that the salt in this substance is decomposed by the iron, by which the surface of the lathe becomes oxydated, and prevented from uniting with the silver or the copper. The sandiver has no action upon the other metals, and therefore does not prevent their union. When the united part is made clean, and hammered with polished tools, the seam cannot be seen on the silvered side. If a yellow line appear, the folder contains too much brass.

Vessels intended to have other forms are generally foldered up in a conical or a cylindrical form, according as the width at the top and bottom of the vessel varies. The metal is so malleable, even in the foldered part, that a skilful workman can give almost any form to a vessel with the hammer.

Mouldings are sometimes formed upon the edges of vessels, which serve to give much strength and stiffness, as well as being ornamental. This operation is performed by an instrument called a swage, see *figs. 3 and 4*. The part *A* lifts up by a joint, and the metal to be swaged is placed between the dies, as shewn in the figures: the part *b* is held in a vice, while the other rests upon it. By striking on the part *A*, at the same time shifting the metal forward, the bead is formed. In *fig. 3*, the part *a* is a guide to regulate the distance of the bead from the edge. The same effect is produced in a neater and more expeditious manner by the rollers, *figs. 8, 9*. *Fig. 10*. is a section, shewing the form of the bead. The two wheels *a, a*, (*fig. 8*.) are placed upon an axis, which have pinions for the purpose, the lower one giving motion to the upper one. The groove in the upper wheel corresponds with the bead in the lower one, and the metal passed between assumes the same figure. This machine, a little varied, may be used as shears to cut the metal into pieces of uniform breadth. A part of the upper wheel *a*, for this purpose must be a little larger, and the edges square and sharp. The lower wheel being put on first, the other must be put on to the other axis, till the face of the enlarged part comes up to that of the other wheel, and in this situation secured by nuts. It will be evident, that if a piece of metal be now placed between them, that the metal will be cut by the projecting part of the upper wheel, in a similar manner to that employed for fitting iron.

The heading and moulding, however, is not at present much used. When prominent parts like these are merely plated metal, they, from being more exposed, soon become bare, and the copper surface is presented.

The greatest improvement ever made in this branch of manufacture, is the introduction of silver edges, beads, and mouldings. Without this means of defending the prominent parts which become so soon bare in the old method, the trade must long since have gone into disgrace, and ultimately to decay. The silver intended to form the prominent and ornamental parts is rolled extremely thin, a superficial inch sometimes not weighing more than 10 or 12 grains.

This is too delicate to have the ornamental form given to it by the swage above described. The two opposite dies being steel, if not very accurately made, would tear silver so delicate as that used for ornaments. It is necessary, therefore, that the sunk part of the die should be steel, and the opposite side lead, as was observed in the stamping, and this is the method generally employed to form these silver ornaments. It seems wonderful, that manufacturers have not thought of doing this by small rollers. It would only require to have the part in which the die is sunk

a wire ring of cast steel, the concave part being a little conical, and made to exactly correspond with a convex cone on one of a pair of rollers, so that by a little force it may be as firm as a solid roller. A ring of lead, or even a straight piece, might act opposite to the die. A much greater variety of dies might be made in this way, than by making dies flat. The dies would cost less, and be better executed. The silver would also run less risk of tearing, than by the stamp or the swage.

When these silver mouldings are formed, and the refuse metal poured off, they are laid upon a level plate, with the hollow side upwards. Small bits of resin are put into the hollow parts, and soft folder melted in with a foldering iron, the point of the same being applied into the groove to keep it in a state of fusion. This is continued till the cavity is quite full. To prevent the folder from accidentally adhering to the convex part, it is previously covered with a paint-like compound of size and whitening. The same expedient is resorted to in all cases where soft folder is employed, or when it is applied to great heat. The soft folder is formed of equal parts of lead and tin. The former metal has so great an affinity for lead, as to require the greatest care to keep these metals separate when one of them is in a state of fusion.

The silver shells, thus filled with soft folder, will now admit of being bent into almost any form. After they are fitted accurately to the place they are to occupy, the part being first made clean and partially tinned, they only require to be secured by temporary fastenings, till the parts can be exposed to a degree of heat capable of melting the folder. This unites the ornament, without leaving any appearance of folder on the outside.

In forming substances which have a massive appearance; such as the feet of tea urns, the handles of vessels, and plated table spoons, no other metal is employed but the sheet. The mass is formed of two shells, which, when put together, form an apparent solid. Each of the concave parts is first filled with soft folder, they are then fitted accurately together, and heat applied till the mass fuses, so that the apparently massive article consists of a shell of plated metal filled with soft folder. Bulky ornaments, in the form of shells and flowers, are frequently put on in this way; some in silver. These have a similar massive appearance to, and strongly imitate, real plate.

All goods formed by hand with the hammer, require great labour in finishing. After hammering the vessel into the proper shape, the marks of the hammer appear like so many flat places. These are removed from the outside of the vessel to the inside, when the inside is concealed, as in tea urns. This is effected by covering either the anvil or the hammer with a piece of the stuff called everlasting. The roughness is transferred to that surface in contact with the everlasting. In hammering plated metal from time to time, it requires to be annealed by heating it red-hot: this discolours both the silver and the copper. These are cleaned by boiling in dilute sulphuric acid, and scowering with Calais sand. The sulphuric acid to the water is in very small proportion. If the silver begins to appear black by boiling, the acid is too much, and must be watered. When the vessels are finished in every respect by the maker, and the surface free from oxyd, it frequently happens that bits of rosin, used with soft folder, adhere to it. This is removed by boiling in a weak solution of pearl ashes. The same is also used for cleaning the surface of tinned copper.

The vessels are now ready for burnishing, a process which we shall soon describe.

Our instructions hitherto have particularly applied to braziers' work; we shall next describe the candlestick-making.

In this branch of the business there is great variety. In the commencement of this trade the object was chiefly to imitate those made of silver, and it began with the prevailing taste of imitating the different orders of architecture. The numerous points and prominences thus introduced, were ill fitted for plated metal, as in a very little time their silver disappeared, which gave them the most shabby appearance possible. This obliged the manufacturers to make them more plain and simple, and it was not till the discovery of the silver edges, that candlesticks of plated metal began to gain respect in the world of luxury and fashion. The stems of candlesticks have been made square; some with sharp, others with rounded corners; others oval, but the greatest number with round stems, which appear to be the most consistent and the most permanent. Of these, the patent telescope candlestick has had the greatest run. This consists in the cylindrical part lengthening and shortening at pleasure, by one tube sliding into the other. In this case the tubes are drawn by machinery, similar to that used for drawing the tubes of telescopes. The feet of candlesticks, or the base, are generally made in a die by the stamp. The neck, which is sometimes small in one part, is also stamped. The dish part of the nozzle or socket is made in a die, and the tube part in the same way as the cylindrical pillar. These, for the sake of neatness and expedition, are generally drawn in the wire drawing machine, whether for sliding or not. Some of these tubes are fluted. The prominent moulding and beads are generally of silver. The different parts are foldered together, some parts with hard and others with soft folder. The branches of candlesticks are formed in two halves, like the tea urn feet, &c. In forming such articles as are made of wire, such as bread baskets, toast racks, and casters, the wire is bent into the given form with a wooden block and a mallet. When pieces require to be foldered together, the joinings must be accurately fitted, in order to prevent the copper from appearing. In these cases hard folder is employed. This branch of plated manufacture admits of extensive application. Wires are capable of great variety of positions. The work lately published by sir James Hall, seems to prove that Gothic architecture has originated in the fanciful forms of bended twigs. The perusal of this work could not fail to give important hints to an ingenious manufacturer of plated wire work.

Plated goods, particularly tea urns, and globular vessels for the same purpose, frequently require to be engraved; but it is obvious that, from the extreme thinness of the plate, the graver would lay bare the copper; and if the plate was so thick all over as to admit of engraving, the articles would be very expensive. Both these evils are obviated, by working an extra plate of silver on to the part to be engraved. This is done while the plate, of which the vessel is made, is in its flat form. The part where the engraving will fall is first scraped clean, and a plate of silver, of similar thickness to that employed for silver edges, is cut to the same size, and also scraped clean. The plated sheet is then laid upon a hot anvil, and the plate of silver laid upon the place prepared. It is first rubbed slowly, but with great pressure, with a polished hammer previously heated, but not so as to affect the polish. The plate will begin to adhere, and it may then be slightly hammered; ultimately it will adhere all over, and may now be hammered on a polished flake, till the whole surface becomes plane, and the piece of silver cannot be distinguished from the rest. This process is on the same principle as the plating of wire, and is similar to weld-

ing two pieces of iron together. It appears practicable that the surfaces of any malleable metals, when clean and heated to acquire a certain degree of softness, are capable of uniting. Most people are familiar with the union of two pieces of lead by pressure, even at the common temperature.

When the different plated goods come out of the hands of the workmen, the metal, although clean, is of a dull white colour, possessing no polish whatever.

This last finish is called burnishing, and is generally performed by females in a distinct set of apartments. The burnishing tools are generally made of blood-stone, and some of hardened steel finely polished. The latter are to burnish the minute parts which cannot be touched by the blood-stone, which are employed chiefly for the greater and interrupted parts.

The bits of blood-stone are let into little cases, made of sheet iron, and then finely polished.

The burnishers, if used dry, would adhere to the silver in some places, and would scratch instead of giving the fine polish intended. This is obviated by frequently dipping the burnishing tool into a solution of white soap. After being burnished they are raised, and lastly wiped with clean sheep's leather.

It is a circumstance much to be regretted, that silver, although it is susceptible of so fine a polish, does not keep its lustre. This is occasioned by the sulphur which comes from sulphurated hydrogen, a gas always existing in the atmosphere. The thinnest coating of any substance will prevent this change. If the surface of silver were coated with a solution of gum arabic or isinglass, the defence will not be perceived, and the silver will never change colour.

We shall conclude this article with a few remarks upon the present mode of plating the ingots intended for sheets. It will be evident, that since the heat in plating must be equal to forming a portion of an alloy of silver and copper, which by its early fusion unites the two surfaces together, the silver will not be uniform in its quality, and by wearing will present an alloy having more than its proper quantity of copper; and will, in consequence, exhibit a base colour. It will be remembered, that the method used for plating the wire ingots does not admit of this inconvenience. The silver will keep its colour to the last. We shall no doubt hear, at some period when the plated manufacturers employ men of talent as platers, that the ingots for rolling will be plated by the method employed for the wire.

PLATER, FELIX, in *Biography*, an eminent physician of the 16th century, was born at Basle in 1536, of the college of which place his father was principal. Here Felix received his early education under his father's eye; and afterwards went to complete his medical studies at Montpellier, where he distinguished himself at an early age, and obtained the degree of doctor in 1556. He then returned to Basle, where he is said to have taken another degree in the following year, and settled in the practice of his profession. His reputation and success were soon equal to the promise of his education; for he was appointed to the chair of medicine in 1560, and became the confidential physician of the princes and nobles of the Upper Rhine. In addition to his medical skill, he possessed an extensive knowledge of anatomy, botany, natural history, and other branches of science, and contributed much by his talents and character to the celebrity of his native university, in which he was a teacher upwards of fifty years. He died in July, 1614, in the 78th year of his age, extremely regretted by his countrymen and his brother-professors. He left the following works: "De Corporis humani structura et usu Libri tres," Basle, 1583 and 1603, folio; "De

Febribus Liber," Francfort, 1597; "Praxeos Medicæ Tomi tres," Basle, 1602; "Observationum Medicinalium Libri tres," ibid. 1614, &c.; "Consilia Medica," Francf. 1615, in the collection of Brendelius; "De Gangrænâ Epistola," in the first century of the letters of Hildanus. After his death were published "Quæstionum Medicarum paradoxarum et eudoxarum Centuria posthuma," Basle, 1625, edited by his brother, Thomas Plater; and "Quæstiones Physiologicæ de partium in utero conformatione," Leyden, 1650.

Thomas Plater, the brother of Felix, also was a professor of medicine at Basle, and had two sons, Felix and Francis, the former of whom occupied successively the chairs of logic and natural philosophy. Eloy Dict. Hist. de la Medecine.

PLATERNETZA, in *Geography*, a town of Slavonia, on the Save; 10 miles from Pofzega.

PLATES, a cluster of small islands among the Bahamas. N. lat. 22° 30'.

PLATESSA, in *Ichthyology*, a name by which Ausonius and some other authors have called the passer-fish, or common plaife. See PLEURONECTES *Plateffa*.

PLAT-FOND, in *Architecture*, the same as fossit.

PLAT-FORM, in the *Military Art*, an elevation of earth, a floor of wood or stone, on which cannon is placed to fire on the enemy.

Such are the mounts in the middle of the curtains. On the rampart there is always a platform, where the cannon are mounted.

It is made by the heaping up of earth on the rampart, or by an arrangement of madders, rising insensibly for the cannon to roll on, either in a casemate, or an attack in the outworks.

Plat-forms are generally laid sloping towards the parapet, nine or ten inches; this declivity carries off the rain, prevents the gun from recoiling so much when fired as it would do if laid level; and, when loaded, it is more easily brought to the embrasure.

In temporary batteries, the plat-forms are made of planks laid across ground-timbers or sleepers, usually five in number, and kept steady by stakes at each end; there is usually a plat-form made to each gun; it is commonly about eighteen feet long, eight feet broad next the parapet, and about fourteen feet broad at the tail, the intermediate spaces between the plat-forms serving for the shot and other necessities. When a plat-form is to be laid on marshy ground, first lay a floor of two or three fascines; cover these with hurdles, twelve or fifteen feet long, and six or seven broad; on these lay a floor of three or four inches of earth, and therein lay the sleepers, and over them the planks. When a battery is built of stone or brick, the plat-form is generally a flat stone pavement ranging the whole length of the battery: this, on account of its resisting the injuries of the weather for a long time, is to be preferred to planks; but in case of bombardment such a plat-form is to be avoided, because the shells will not only break the pavement, but also, by driving about the broken stones, do much mischief to the troops.

All practitioners are agreed, that no shot can be depended on, unless the piece be placed on a solid plat-form; for if the plat-form shakes with the first impulse of the powder, it is impossible but the piece must likewise shake; which will alter its direction, and render its shot uncertain. To prevent this accident, the plat-form is usually made extremely firm to a considerable depth backwards, so that the piece is not only well supported in the beginning of its motion, but likewise through a great part of its recoil. However, it is sufficiently obvious, that when the bullet is separated from the piece, it can be no longer affected by the trembling of the

piece or plat-form; and by a very easy computation it will be found, that in a piece ten feet in length, carrying a bullet of twenty-four pounds, and charged with sixteen pounds of powder, the bullet will be out of the piece before it has recoiled half an inch; whence, if the plat-form be sufficiently solid at the beginning of the recoil, the remaining part of it may be much lighter, since its unsteadiness beyond the first half inch will have no influence on the direction of the shot: and hence a more compendious method of constructing plat-forms may be found out. New Princip. of Gunnery, p. 42.

PLAT-FORM, in *Architecture*, is a row of beams, which support the timber-work of a roof, and lie at the top of the wall where the entablature ought to be raised.

PLAT-FORM is also used for a kind of terrace, or broad, smooth, open walk, at the top of a building, from whence we may take a fair prospect of the adjacent country.

Hence an edifice is said to be covered with a plat-form, when it is flat at top, and has no ridge.

Most of the oriental buildings are thus covered, as were all those of the ancients. Cæsar was the first among the Romans who procured leave to build his house with a ridge or pinnacle.

PLAT-FORM, in a *Man of War*. See ORLOP.

PLATIA, in *Geography*, a small island in the gulf of Engia; 18 miles N.W. of Engia.

PLATIASMOS, of πλατίζω, *I dilate*, formed from πλατίζω, *wide*, a word used by many authors to express a fault in pronunciation, owing to a person's opening his mouth too wide, and thence speaking indistinctly.

PLATICORIA, formed of πλατίζω, *wide*, and κόρη, *pupil*, a word used by medical writers to express a preternatural dilatation of the pupil of the eye, usually owing to a paralytic disorder.

PLATILLA, LA, in *Geography*, a mountain of Spain, N.W. of Molina; celebrated for its mines of copper.

PLATINA, BARTOLOMEO, in *Biography*, an historian who flourished in the 15th century, was born in 1421, at Piadena, in the Cremonese, from which place he chose to take his surname, rather than from that of the family to which he belonged, which was De Sacchi. He was brought up to the military profession, and bore arms some time before he engaged in literary studies, which he probably first pursued at Mantua. He accompanied cardinal Francesco Gonzaga to Rome, where Pius II. aggregated him to his new college of abbreviators. He was deprived of his post by Paul II., who dissolved the college, and turned on the world, without any means of support, seventy learned men, who had been employed in it. Platina, who had more spirit than the others, wrote to the pope, threatening him with an appeal to a council. This menace enraged Paul to such a degree, that he threw Platina into prison, where he was kept four months, till he obtained his liberty by the intercession of cardinal Gonzaga. Three years after this he underwent a more severe treatment, on occasion of a contest between the same pope and the Roman academy of Pomponio Leto, of which Platina was a member. It appears from Platina's own account of this transaction, that he himself was apprehended while at supper with cardinal Gonzaga, brought before the pope, and urged with threats to confess a supposed conspiracy against him; and that he was committed to prison, because he avowed his perfect innocence of the crime laid to his charge. He and several of his friends were put to the torture twice, but when nothing could be found to criminate them, they were gradually liberated. Platina obtained from Sixtus IV. a recompence for his sufferings, in the honourable post of keeper of the Vatican library, which he held till his death in 1481. In the following

lowing year there was a solemn commemoration of the anniversary of his death. He was considered as one of the ablest scholars of his time. His most celebrated work was the "Lives of the Roman Pontiffs," composed in Latin with great elegance and energy. "It was," says the historian, "one of the first pieces of biographical history which gave an example of good criticism." He frequently examines, doubts, conjectures, cites ancient documents, refutes errors, and sometimes, as might be expected, commits them himself. His greatest fault is the acrimony with which he speaks of some contemporary popes, among whom it may well be supposed that he does not spare Paul II. He was likewise author of the "History of Mantua," from its origin to the year 1464. His other writings are chiefly dialogues on points of moral philosophy, and short treatises on miscellaneous topics: among the latter is one on the culinary science; and what renders this still more curious is, that it is dedicated to cardinal della Rovere. Moreri. Gen. Biog.

PLATINA, or *little silver*, from the Spanish word *plata*, silver; called also *platinum* by some late English chemical writers; in French *le platine*.

Platina, not being liable to oxydation by the agencies of heat, air, or moisture, is usually classed with gold and silver, which possess the same property; and these three metals were formerly, and are still sometimes called the *noble* metals, in opposition to the *base* metals, or those which are oxydable by air and moisture.

It is only about sixty years since platina was introduced into Europe. The first specimens which reached this country were brought from America by Mr. Wood in the year 1749; in the following year some others were presented to the Royal Society by Dr. Brownrig, soon after which Mr. Wood, Dr. Lewis, Bergman, and other chemists, began to examine the properties of this metal. Of late years, Morveau, Jeannetty, Vauquelin, Descotils, and more especially Wollaston and Tennant, have greatly contributed to our knowledge of this substance. The free importation of platina into Europe was for a long time jealously prevented by the Spanish government, from an apprehension that advantage might be taken of its specific weight, and other general properties, to adulterate gold with it, an objection which the present improved state of chemistry has entirely removed.

Natural History.—Platina was for a long time supposed to be the exclusive produce of South America, where it is found in various places, particularly on the banks of the Rio del Pinto, in the district of Choco in Peru; in the mines of Taddo, near the Rio de la Plata in the same district; in the mine of Santa Fé near Carthagena, in New Granada, (Klaproth's Dictionary of Chemistry, iii. 363.) and also, as Dr. Wollaston has lately shewn, in a new mineral from the gold mines in Brazil. (Philos. Transf. 1809, part ii.) Of late years, however, Vauquelin has also discovered platina in Europe, in a grey silver ore from the mines of Guadalcanal, in the province of Estramadura in Spain. Ann. de Chimie, vol. lx.

The natural history of this metal is but imperfectly known. But it is well ascertained that platina is found in its native state in small fragments or grains, loosely mixed with the sand of certain streams, always accompanying gold, and generally interspersed with a variety of other metallic and heavy earthy bodies. The greater part of these impurities is separated from the ore in America; so that when it reaches Europe, it appears in the form of pretty uniform metallic grains, which are neither round nor angular, but are somewhat flattened and smooth; their colour is a greyish-white;

they appear to be partly attracted by the magnet, which is no doubt owing to the iron always mixed with them. Their size varies from that of fine sand to that of a pea. No veins or considerable masses of pure platina have ever been discovered. Some fragments, however, weighing from 10 to 40 grains, have occasionally been found, and are preserved as mineralogical curiosities. An extraordinary large specimen of this kind, exceeding the size of a pigeon's egg, is said to have been given by Humboldt to the National Museum of France; it weighs 1088 grains, and its specific gravity is 15.6. It was found in 1800, in the mines of Taddo, in the district of Choco. Klaproth's Dictionary of Chemistry.

Platina, in the granular form just described, which is properly that of an ore, still containing a variety of impurities, fluctuates in its specific gravity between 15 and 17. In one instance Dr. Wollaston saw it reach 17.7; but this is the heaviest specimen he ever met with. (Phil. Transf. 1805.) This ore scarcely contains 80 *per cent.* of the pure metal, and sometimes much less; the remainder being a mixture of a great variety of other minerals, such as gold, silver, mercury, iron, copper, lead, chrome, titanium, (Fourcroy and Vauquelin, Annales du Musée, tom. iii.) and, what is very remarkable, no less than four new metals, iridium, osmium, rhodium, and palladium, the existence of which was not even suspected till a few years ago, and which have never been found elsewhere. Various earthy minerals, and especially quartz and hyacinth, are also occasionally found mixed with this ore in different proportions. Wollaston, Phil. Transf. 1805.

Purification of the Ore.—Before we describe the properties of platina as a metal *sui generis*, it will be proper to relate the manner in which it is obtained, in a pure and malleable state, from the granular mixture just described.

Various difficulties occur, not only in separating the platina from the other bodies with which it is mixed in the ore, but also, and principally, in bringing the metal to the state of a consolidated malleable mass.

With regard to the separation and purification of platina, this might be effected in an imperfect manner, by selecting and picking out the grains of platina, which are discernible from the other ingredients by their external characters. This, however, would be a most tedious process, and the grains of platina would still be found to contain various impurities, and particularly iron, which would prevent their subsequent consolidation into a malleable mass. Besides, the great infusibility of platina would render such a mode of consolidation, if not impracticable, at least extremely difficult. After trying a variety of methods, more or less imperfect, for the purification of platina, chemists have generally adopted the following process.

The first step consists in separating from the platina ore small globules of quicksilver, which are generally found mixed with it, in consequence of a process of amalgamation, which it undergoes in America, in order to separate the gold from it, when it is first collected. These are easily driven off by a moderate heat. A considerable portion of the other impurities may be easily separated, in consequence of their greater levity: thus, by blowing upon a quantity of these grains, spread over an inclined plane, with a common pair of bellows, the lighter particles, such as those of quartz and iron ore, are readily driven off from those of platina.

The gold, some portions of which always escape the process of amalgamation just mentioned, may be next separated by pouring a small quantity of dilute nitro-muriatic acid upon the grains of crude platina. The quantity of gold thus taken up commonly amounts to about a quarter of a grain

grain from each ounce of the ore; but as much as 7, or in one instance as much as 13, parts of gold are said to have been obtained from 100 parts of the ore. (Proust, *Ann. de Chim.* vol. xxxviii.) In this first operation, a small quantity of platina and other ingredients will also be dissolved; but the gold may be easily precipitated from this solution by sulphate of iron, and the platina by muriate of ammonia.

After the separation of the gold, nitro-muriatic acid, being poured on the remaining mass, will dissolve it, with the exception of a small quantity of black matter (about 3 per cent.), which was formerly mistaken for plumbago, but is now proved to be a compound of osmium and iridium, two of the four new metallic bodies before mentioned, which were discovered a few years ago by Mr. Tennant. See IRIDIUM and OSMIUM; and *Phil. Transf.* for 1804.

These two metals Dr. Wollaston has since shewn to exist also in the crude platina ore, united together in the form of distinct minute crystals, and dispersed through the other grains, from which they can be distinguished and picked out without difficulty. (*Phil. Transf.* for 1805.) Muriate of ammonia being now added to the solution, the platina is precipitated in the form of a yellowish powder, which is a compound of muriatic acid, ammonia, and platina, or an ammoniaco-muriate of platina.

The remaining solution, after the platina has been separated from it, still contains, besides iron, minute quantities of various other substances, amongst which the two other metallic bodies, palladium and rhodium, were discovered by Dr. Wollaston. *Phil. Transf.* for 1804 and 1805. See also PALLADIUM and RHODIUM.

Consolidation.—Having now brought the platina to the state of a salt, the next object is to restore the platina, thus purified, to its metallic state, and to consolidate it into a malleable mass. This, from the great infusibility of platina, has long been a matter of considerable difficulty and labour; and although the process has been, of late years, considerably improved and simplified, it still requires from the operator a certain degree of dexterity and experience.

Before we describe the improved process in question, it may be proper to notice the earlier and less successful attempts, which were made for the consolidation of platina.

It had been long discovered that arsenic readily united with platina, and formed with it an alloy of great fusibility. An alloy, therefore, was made of crude platina and arsenic; and the latter metal, being easily volatilized, was driven off by heat; whilst the iron, being oxydated during the process, was also separated from the mass; so that the platina was left in an impure, but malleable state. This mode of consolidation of the crude ore by means of arsenic, first proposed by Aehard and others, was brought to a great degree of improvement by Jeannetty, a working silversmith of Paris (*Ann. de Chim.* vol. xiv.); and utensils of platina were procured by his method at a reasonable price. But the platina so prepared was far from being pure; for it had a lower specific gravity, and still contained small portions of arsenic, iron, lead, copper, besides the four new metals above mentioned; and it did not, therefore, possess in a sufficient degree those qualities which render platina so useful for its various purposes.

The late improvements in the process consist principally in obtaining the platina, not immediately from the crude ore, but from the ammoniaco-muriate above mentioned. By applying heat to this salt, the muriated ammonia is gradually expelled, and the metal passes to the state of a spongy mass, which, by patient and repeated heating and hammering in a strong mould, is at last brought to a malleable

state. Count Mouffin Pouschkin was, we believe, the first person who proposed to prepare platina from the ammoniaco-muriate (*Nicholson's Journal*, vol. ix.); but he used mercury in the process. An amalgam was formed with the spongy mass above described; and by successively heating and hammering this amalgam, the mercury was driven off, and the metal was consolidated into a malleable mass. This method was afterwards farther simplified by other chemists, the intervention of mercury being altogether dispensed with. One of the earliest accounts of this last improvement was published by Mr. Knight. (*Phil. Mag.* vol. vi.) But the most perfect description of this mode of working platina, that has yet been published, is that given by Mr. Cook, in Aikin's Dictionary, vol. ii. p. 233, which, being scarcely susceptible of abridgment, we shall transcribe *verbatim*. "The platina being dissolved in nitro-muriatic acid, the liquor is to be filtered through clean white sand, in order to separate the black powder which floats among it. The clear solution being then decomposed by sal-ammoniac, the yellow precipitate is to be collected, moderately well washed in warm water, and dried. It is then to be distributed into saucers, which are placed in a small oven constructed for the purpose, where they are exposed for a short time to a low red heat, in order to bring the platina to the metallic state, and drive off by sublimation the greater part of the muriated ammonia. When withdrawn, it is a spongy mass of a grey colour. About half an ounce of the platina in this state is to be put into a strong iron mould, about 2½ inches long, by 1½ wide, and is to be compressed as forcibly as possible, by striking with a mallet upon a wooden pestle, cut so as accurately to fit the mould: another half ounce is then added, and treated in the same manner; and so on, till six ounces have been forced into the mould. A loose iron cover, just capable of sliding down the mould, is then laid upon the platina, and, by means of a strong screw press, almost every particle of air is forced out from the platina. This is a part of the process that requires especial care; for if any material quantity of air is left in the mass, the bar into which it is formed is very apt, in the subsequent operations, to scale and be full of flaws. The pressure being duly made, the mould is to be taken to pieces, and the platina will be found in the form of a dense compact parallelepiped. It is now to be placed in a charcoal forge fire, and heated to the most intense white heat, in order completely to drive off the remaining ammoniacal muriate. This being done, it is to be quickly placed on a clear bright anvil, and gently hammered in every direction by a clean hammer. This is to be repeated several times, at the end of which the mass will be perfectly compact, and fit to be laminated or wrought in any other manner that the artist chooses. It is to be observed, that while the platina is heating, it must lie loose in the fire; for if it were held by the tongs, they would infallibly become welded to the platina, and thus greatly damage it. By the time that the platina is thus drawn down to a compact bar, it will be covered by a somewhat reddish semi-vitreous crust, proceeding chiefly from particles of the ashes melted down upon it, and extended over its surface by the hammer. To remove this, the bar, being made red-hot, is to be sprinkled over with pulverized glass of borax, and then kept for a few minutes at a white heat. When moderately cool, it is to be plunged into dilute muriatic acid, by which the borax and other vitreous matter will be dissolved, leaving the platina with a perfectly clean white surface."

It is by methods of this kind that utensils of platina, though still expensive, have gradually become less scarce, and are now much used in chemical manipulations. This

PLATINA.

metal may now (1814) be purchased in bars at the rate of 15s. an ounce; whilst a few years ago, its price was between two and three times as great. The price of platina, in grains, fluctuates between 3s. and 4s. an ounce.

Physical and Chemical Properties of Platina.—The colour of pure platina is between silver-white and steel-grey; its ductility and malleability are very great; it can be brought to the state of laminae of almost any thinness by being pressed between rollers; and it can also be drawn into wire of extreme minuteness. In hardness, platina is scarcely inferior to iron, and it is susceptible of a fine polish; so that coin or medals made of pure platina would admit of very fine impressions, and, like gold, would not be liable to alteration.

The specific gravity of malleable platina is generally found to be about 21.3, never rising to 22 or 23, as some French chemists have erroneously stated; but being subject to slight variations according to the different degrees of density it has received during the process of hammering. Gold, the next heaviest metal, is 19.3; and therefore the density of platina is much more considerable than that of any other known substance. In its native state, however, the specific gravity of the platina ore does not, as was observed before, exceed 17.7; whilst that of the grains of iridium and osmium above mentioned is 19.15, which is a higher degree of specific gravity than that of any other known native substance.

The great ductility of platina has been put in a very striking light by some recent experiments of Dr. Wollaston. (Philos. Transf. for 1813.) This philosopher, whose dexterity in mechanical operations is no less conspicuous, than his views in natural science are acute and refined, succeeded, by a new and ingenious process, in drawing platina wire so small as the $\frac{1}{100000}$ th, or even $\frac{1}{800000}$ th part of an inch in diameter; and the tenacity of the latter was still such as to support 14d grain without breaking. The method by which Dr. Wollaston succeeded in obtaining such very fine wire was shortly this: a piece of platina wire, previously drawn, by the usual means, to the $\frac{1}{1000}$ th of an inch, was fixed longitudinally in the centre of a short cylindrical mould of $\frac{1}{4}$ d of an inch in diameter; the mould being afterwards filled with melted silver, a cylinder of this metal was obtained, having the platina wire in its centre. Now it is evident, that by drawing the silver rod to $\frac{1}{1000}$ th, the platina wire was reduced to $\frac{1}{1000000}$ th of an inch; and this was repeated, till, by a succession of similar reductions, the extremely small wires above-mentioned were obtained. The silver coating was then removed by dilute nitrous acid, which left the platina wire untouched. Very fine wires of this kind have been employed by Dr. Wollaston to measure the intensity of very small Voltaic batteries, and have also been applied to some optical purposes.

But the most characteristic property of platina, from which it derives its great value, is that of being neither oxydable by the combined influence of heat, air, and moisture, nor capable of being fused by the most powerful furnaces: on this account crucibles and other utensils are made of this metal, which are singularly useful in chemical experiments. In the state of wire, however, it can be fused and reduced to the state of globules by a very powerful Voltaic battery; and Dr. Marcet has shewn that the same may be effected with great ease by the flame of a spirit lamp impelled by a current of oxygen gas. (Thomson's Annals of Chemistry, vol. ii.) Platina which has been thus melted, appears to be somewhat more ductile and tenacious; and it was from globules melted by the latter method, that the extremely fine wire above-mentioned was obtained. Platina wire, provided it be exceedingly fine, is

also capable, as Tennant and Berzelius have lately observed, of being melted by the common blowpipe; but the globule thus obtained is so minute as to be scarcely ponderable.

Although platina can only be fused in very small quantities, whatever method be employed, it possesses, at a white heat, the valuable property of welding like iron; so that two pieces, when heated to the proper point, may be forged together and united into one uniform mass. This, however, is not very easily effected, on account of the impurities which arise from the fuel and impede the operation.

Platina is not acted upon by any of the acids, except by the nitro-muriatic or oxymuriatic. If two parts by weight of aquafortis of 35°, Beaumé, be mixed with six parts of muriatic acid of 15°, and digested with this laminae of platina, nitrous gas is given out, and about one part of the metal is dissolved. (Proust, Ann. de Chim. vol. xxxviii.) This solution is of a reddish-orange colour, and gives an indelible stain to the skin. The muriate of platina is capable of being crystallized by careful evaporation; and by the application of heat alone, it may be reduced first to the state of oxyd, and afterwards to the pure metallic state.

Platina, thus dissolved in nitro-muriatic acid, has the property, (first discovered by Lewis, and already alluded to in describing the purification of platina,) of being precipitated by muriate of ammonia, in the form of a triple salt, or ammoniaco-muriate of platina. This salt, if pure and unmixed with other metals, is of a yellow colour; but it is said to assume a brick-red colour if combined with the oxyd of iron, or the other metals which are mixed with crude platina. The ammoniaco-muriate of platina is but very sparingly soluble in water. It is decomposed by heat alone, leaving behind about 42 per cent. of its weight of platina; so that, in this instance, the metal passes from the state of salt to the reguline state, without appearing in the intermediate form of oxyd.

Both soda and potash, in precipitating platina from its solution, also form triple salts, the general properties of which are analogous to those of the former. There is, however, this remarkable difference between the action of the two fixed alkalies on muriate of platina, that solutions of this salt, however dilute, are instantly precipitated by potash or its compounds; whilst soda does not produce any precipitates from them, the soda-muriate being much more soluble than the two others, both in water and alcohol, and requiring considerable concentration for its crystallization. A solution of platina, therefore, affords an easy test of discrimination between the two fixed alkalies, which are not always easily distinguishable by their other properties.

Solutions of muriate of platina are decomposed by several metallic salts, particularly by solution of muriate of tin, a very minute quantity of which will impart to solutions of platina a bright red colour. Platina, however, is not precipitated by the gallic and prussic acids, or by their compounds. Sulphuretted hydrogen separates platina from its solution in the form of a brown precipitate.

The action of the caustic fixed alkalies on platina, at high temperatures, is considerable. The metal is corroded and partly dissolved, a circumstance which, of course, limits the use of platina crucibles in the analysis of earthy minerals. Nitre, likewise, as Mr. Tennant has shewn, is capable of acting upon, and partly dissolving platina, at high temperatures.

Platina is capable of combining, by fusion, with most of the metals. It forms alloys with gold, with silver, with lead, &c., many of which have been examined by Mr. Hatchett. (Philos. Transf. 1803.) The alloy of platina and gold, in particular, possesses properties, especially

in regard to its hardness and malleability, which may some day be found useful. The alloy of platina and silver is moderately fusible and very malleable; but when heated to redness, its surface becomes uneven, and incapable to be wrought. Lead combines readily with platina at a full red heat, forming a malleable and easily fusible alloy. Mercury acts but slowly upon platina in its malleable state; but the triple salt, or ammoniaco-muriate, readily combines with mercury by trituration, forming solid and brilliant amalgams.

Platina does not appear to be capable of combining with sulphur; but it unites readily with phosphorus, forming a phosphuret of much greater hardness and fusibility than the metal itself. When exposed to a strong fire, the phosphorus is melted and volatilized; a circumstance which has suggested the idea of purifying platina by the intervention of phosphorus. Pelletier, *Ann. de Chim.* xiii. 105.

Platina has not hitherto been extensively used in the arts on account of its high price; but its utility is becoming every day more generally acknowledged. From its great infusibility and unalterability in particular, crucibles, and other utensils made of this metal, are of incalculable value in analytical researches. Many facts are daily brought to light by means of platina instruments, which, without it, might perhaps ever have escaped notice. The remarkable slowness with which platina conducts caloric, increases its utility in many chemical manipulations. Thus small tongs or spoons, or thin slips of laminated platina (which often answer the purpose better than spoons) may be held with the hand by one end, whilst the other extremity is exposed to an intense heat, without the heat reaching the fingers. The touch-holes of guns are now generally made of this metal, instead of gold, which was formerly used for this purpose. From the circumstance of platina not being tarnished by air or moisture, nor scarcely by any chemical agent, mirrors for reflecting telescopes have been made of this metal; and instruments of various kinds might, no doubt, be covered over or plated with it with great advantage.

Guyton Morveau has recommended platina as a substance likely to afford a new and useful means of ascertaining high temperatures, by its dilatations and contractions, which he believes to bear an exact proportion to the changes of temperature. Platina being nearly infusible and unalterable by heat and air, would seem, on these accounts, likely to be a valuable pyrometrical substance. Morveau's contrivance consisted in connecting a bar of platina with a very simple machinery, by which the elongations or contractions of the portion of the apparatus which was exposed to the heat, were rendered conspicuous, and could be accurately measured. *Ann. de Chim.* tom. xlvi.

Platina vessels have, in a few instances, been used upon a large scale in manufactories, especially in the concentration of vitriolic acid, which is usually carried on in large glass retorts, containing as much as 50 or 60 pounds of acid. The bursting of these vessels, an accident both dangerous and expensive, and by no means uncommon, may be totally avoided by substituting vessels of platina. A vessel of this metal, containing 300 pounds of vitriolic acid, has, for many years, been used for this purpose in the manufactory of Mr. Sandman in the Borough. Still larger vessels have since been used for the same purpose by other manufacturers. The distillation is also more easy, because the vessel is set upon a naked fire, instead of being placed in a sand bath.

The metallic glazing, with which some kinds of earthen ware and porcelain utensils have, for a few years past, been

coated, is obtained from oxyd of platina. (*Klaproth's Dictionary*, iii. 380.) This glazing has a brilliant silvery, or rather steel-grey lustre. The ammoniaco-muriate of platina is said to be commonly employed in British potteries for this purpose.

PLATISMA, in *Botany*, from *πλατῆς*, broad, the name of the nineteenth section of Lichens, in the *Prodromus* of Acharius. See LICHENES.

PLATNER, JOHN ZACHARIAH, in *Biography*, an able physician, was born at Chemnitz, in Misnia, in August 1694. His father, who was one of the principal merchants of the place, intended to make him his successor in the same line; but resolved to enlarge his mind by a liberal education, and to give him a knowledge of ancient languages and philosophy, before he led him into commercial pursuits. But young Platner possessed a delicate constitution; and, partly on this account, and partly in consideration of the rapid progress which he made in his studies, his parents relinquished their original design, and consented that he should direct his attention to medicine, for which he had manifested a strong inclination. He repaired, therefore, to Leipzig in 1712, where he pursued his studies for the space of three years, when the reputation of the university of Halle induced him to visit its schools. During the following winter, he studied mineralogy and metallurgy in the celebrated mines of Chemnitz; after which he returned to Halle, and received the degree of doctor in September 1716. The pursuit of professional knowledge became his passion, and he spent four years in visiting the most celebrated seats of learning in Europe. At Paris he particularly attended to anatomy and surgical operations, especially to those relative to diseases of the eye, in which he is said by Haller to have acquired such dexterity, as to have succeeded in the cure of some, which the celebrated St. Ives had failed to relieve.

He now determined to settle at Leipzig, and accordingly fixed himself in that city in 1720; and his great professional acquirements were speedily rewarded by public acknowledgements of their value. In 1721 he was appointed professor extraordinary of anatomy and surgery. In 1724 he obtained the chair of physiology, which had become vacant by the death of Rivinus; in 1737 he was promoted to the professorship of pathology; and in 1747 to that of therapeutics. He was also nominated perpetual dean of the faculty, and consulting physician to the court of Saxony. He did not live long, however, to enjoy these flattering distinctions; for he was carried off suddenly, on the 19th of December 1747, in the fifty-fourth year of his age, by a paroxysm of asthma. He had visited his patients on the morning of that day, and given his lecture after dinner; and upon returning home, about six in the evening, was seized with the fatal fit.

He left only three different works, the first of which, entitled "*Institutiones Chirurgiæ Rationalis, tum medicæ, tum manualis*," Leipzig 1745, was published by himself. It passed through several editions. The second, entitled "*Opusculorum Chirurgicorum et Anatomicorum Tomi duo: Dissertationes et Prolusiones*," *ibid.* 1749, was edited by his son, Frederic Platner, a professor of law. And the third, entitled "*Ars medendi singulis morbis accommodata*," *ibid.* 1765, which had been bequeathed by the author to his pupil J. B. Boehmer, upon condition that it should not be published, was printed by a bookseller, Fritsch, into whose hands a copy of it fell eighteen years after the author's death. *Eloy Dict. Hist. de la Med.*

PLATO, a Greek comic poet, who flourished about the close of the fifth century B.C., was contemporary with Aristophanes and Euripides. He is said to have left twenty-

twenty-eight comedies, of which the titles of many are to be found in Athenæus, Pollux, and other writers. Of his works, only a few fragments remain, some of which are of the epigrammatic kind.

PLATO. See PLATONISM.

We shall here observe, that Plato, Aristotle, Aristoxenus, and Plutarch, were for ever complaining of the corruption and degeneracy of music. The pious Plato, indeed, regarded it as fit only for the gods, and their celebration in religious ceremonies, or as a vehicle for religious and moral lectures in the education of youth; and with a methodical spirit censured all such as was used in theatres, social festivity, or domestic amusement: but modern divines might, with equal propriety, declaim against the profane use of bread as an aliment, because it is administered in the most solemn rite of our religion. A line should certainly be drawn between the music of the church and of the theatre; but totally to silence all musical sound, except upon solemn occasions, seems to border upon downright fanaticism.

With respect to perfection and depravity, there is nothing so common among musical disputants, as for the favourers of one sect to call that *degeneracy*, which those of another call *refinement*. But Plato seems to have been always too fond of ideal excellence in every thing, to be satisfied with any other. His complaints of the degeneracy of music, may be seen in his third Book of Laws. The poets, indeed, never fail to charge the corruption of music upon its professors, yet Plato throws the blame upon the poets themselves. "The music of our forefathers," says he, "was divided into certain species and figures. Prayers to the gods were one species of song, to which they gave the name of hymns: opposed to this was another species, which, in particular, might be called threni; another, pæones; and another, the birth of Dionysius, which I hold to be the dithyrambus: there were also citharædic nomi, so called, as being still another song. These, and some others, being prescribed, it was not allowable to use one species of melos for another. But, in process of time, the poets first introduced an unlearned licence, being poetic by nature, but unskilled in the rules of the science, trampling upon its laws, over attentive to please, mixing the threni with the hymns, and the pæones with the dithyrambi, imitating the music of the flute upon the cithara, and confounding all things with all." Plat. de Legibus, as translated by Sir F. H. E. Stiles. Though it was Plato's opinion, that the government of a state, and the morals of a people, would be affected by a change in the national music, yet this was not the opinion of Cicero, who in many other particulars is a rigid Platonist: "Change," says this orator, "the government or customs of a city, and it will certainly change the music." De Legib. lib. iii.

It has been said by many writers, both ancient and modern, that Plato was deeply skilled in the music of his time; but it does not appear that his claims to skill in this art extend further than to mere theory, or a very little more. Plutarch, indeed, in his dialogue, proves his profound musical science; but how? By a long passage from his Timæus, in which he applies musical ratios to the soul.

However this may have been, it is difficult to refrain from numbering this philosopher, together with Aristotle, Aristoxenus, and Plutarch, though such illustrious characters, and, in other particulars, such excellent writers, among the musical grumblers and croakers of antiquity. They all equally lament the loss of good music, without considering that every age had, probably, done the same, whether right or wrong, from the beginning of the world; always throwing musical perfection into times remote from their own, as

a thing never to be known but by tradition. The golden age had not its name from those who lived in it.

Aristotle, indeed, complains of degeneracy in a more liberal way: "every kind of music," says he, "is good for some purpose or other; that of the theatres is necessary for the amusement of the mob; the theatrical transitions, and the tawdry and glaring melodies in use there, are suited to the perversion of their minds and manners, and let them enjoy them."

The complaints of Aristoxenus are more natural than those of Plato and Aristotle; for he was not only less a philosopher, but more a musician; and, as a professor, and an author on the subject of music, he must have had rivals to write down. Hesiod says that bards hate bards, and beggars beggars. And it has been the practice for writers on music, in all ages, to treat their contemporaries with severity and scorn. Gaspar Printz inserts in his book a canzonet in four parts, in which every rule of composition is violated, and calls it modern; as if error was always new. But besides a natural tendency in human nature, or at least in the nature of authors, towards envy and malignity, Aristoxenus had a system to support, which is usually done at the expense of moderation, truth, and every thing that stands in its way; for, like the tyrant Procrustes, the builder of a system, or the defender of an hypothesis, cuts shorter what is too long, and stretches to his purpose whatever is too short.

The music of the Greeks, in the time of Aristoxenus, was too remote from perfection to be much injured by innovation and refinement; and yet Athenæus gives a passage from a work of this writer, now lost, in which he makes the following complaints: "I, and a few others, recollecting what music once was, and considering what it now is, as corrupted by the theatre, imitate the people of Possidonium, who annually celebrate a festival after the Greek manner, in order to keep up the memory of what they once were; and before they depart, with tears deplore the barbarous state into which they are brought by the Tuscans and Romans."

Though Aristoxenus lived with Alexander the Great, with Plato, and with Aristotle, when all other arts and sciences had arrived at their greatest degree of force and refinement; yet music, from whatever cause, does not seem, at that, or at any time, to have kept pace with other arts in its improvements: at least, it did not in Italy; nor, indeed, in England or France, if we compare the poetry of Milton with the music of Henry Lawes, or the writings of Racine and Boileau, with the compositions of Lully.

PLATOBERG, in *Geography*, a mountain of France, in the department of Mont Tonnerre; four miles N. of Landau.

PLATONIA, in *Natural History*, a name given by the modern Greeks to the *prox* of Aristotle, and of other ancient writers in that language. This is the *cervus platyceros*, or broad-horned stag. Some have translated this *dama*; but they are to be understood in this as meaning the *dama* of their own times, not that of the ancients; that being the *isarus*, or chamois-goat, not any animal of the stag kind, or by any means meriting that title.

PLATONIC, something that relates to Plato, his school, philosophy, opinions, or the like.

PLATONIC *Bodies*, are the same with what we otherwise call regular bodies.

PLATONIC *Love* denotes a pure spiritual affection, subsisting between the different sexes, abstracted from all carnal appetites, and regarding no other object but the mind, and its beauties; or it is even a sincere disinterested friendship

subsisting between persons of the same sex, abstracted from any selfish views, and regarding no other object but the person.

The term took its rise from the philosopher Plato, a strenuous advocate for each kind.

The world has a long time laughed at Plato's notions of love and friendship. In effect, they appear arrant chimeras, contrary to the intentions of nature, and inconsistent with the great law of self-preservation; into which love and friendship are both ultimately resolvable.

PLATONIC Year, or the *great year*, is a period of time determined by the revolution of the equinoxes, or the space in which the stars and constellations return to their former places, in respect of the equinoxes.

The Platonic year, according to Tycho Brahe, is 25816; according to Ricciolus, 25920; and according to Cassini, 24800 years. See *PRECESSION of the Equinoxes*.

This period, which is more than five times the age of the world, once accomplished, it was an opinion among the ancients, that the world was to begin anew, and the same series of things to return again.

PLATONISM, the doctrine and sentiments of Plato and his followers, with regard to philosophy, &c.

The founder of this system of philosophy, Plato, the son of Aristo, was an Athenian, related by his father to Codrus, and by his mother to Solon; born in the island of Ægina, where his father resided after it became subject to Athens, on the seventh of Thargelion, in the first year of the 88th olympiad, B.C. 428, or, as it may be more accurately fixed, in the third year of the 87th olympiad, B.C. 430.

He gave early indications of a distinguished genius; and whilst he was young he was instructed in the rudiments of letters by the grammarian Dionysius, and trained in athletic exercises by Aristo of Argos. He applied with industry to the study and practice of painting and poetry. In the latter he made such proficiency as to produce an epic poem, which, however, upon comparing it with Homer, he committed to the flames; and at the age of 20 years he composed a dramatic piece, which he delivered to the performers in order to its being exhibited on the theatre; but in the mean while he became acquainted with Socrates, and so much enamoured of his philosophy, that on the day before it was to have been represented to the public he withdrew it, and gave up all ideas of poetical distinction. After having spent his youth in exercises of the body, painting, poetry, and music, he became, at the age of twenty years, a disciple of Socrates, and applied himself wholly to the study of wisdom. It is supposed, that he received the first tincture of philosophy from Cratylus and Hermogenes, who taught the systems of Heraclitus and Parmenides. But having become a stated disciple of Socrates, he remained with him eight years. Blending, however, foreign tenets with those of his master, and grafting upon the Socratic system opinions which he had taken from some other stock, he occasionally displeased the followers of Socrates, and sometimes gave Socrates himself occasion for complaint. Nevertheless, he retained a zealous attachment to this master, and when he was summoned before the senate, Plato undertook to plead his cause, and began a speech in his defence, which the partiality and violence of his judges would not allow him to prosecute. After the condemnation of Socrates, he presented him with money sufficient for redeeming his life, which, however, this eminent teacher of wisdom refused to accept. During his imprisonment, Plato attended him, and was present at a conversation which he held with his friends concerning the immortality of the soul, the sub-

stance of which he afterwards committed to writing, in the beautiful dialogue entitled "Phædo," intermixing occasionally his own opinions and language. Upon the death of his master he withdrew, with several other friends of Socrates, to Megara, where they were hospitably entertained by Euclid, and remained till the ferment at Athens subsided. Under Euclid he studied the art of reasoning, and probably increased his fondness for disputation. With a view of furnishing himself with all the knowledge which the age in which he lived could supply, he travelled into every country which was likely to answer any useful purpose to him in this respect. In that part of Italy called Magna Græcia, there was a celebrated school established by Pythagoras, and here he was instructed in the mysteries of the Pythagorean system, the subtleties of which he afterwards too freely blended with the simple doctrine of Socrates. He next visited Theodorus of Cyrene, in order to be instructed in mathematical science; and he then determined to study astronomy, and other sciences, in Egypt. Under the disguise of a merchant, and seller of oil, he traversed the whole kingdom of Artaxerxes Mnemon, deriving information from the Egyptian priests concerning their astronomical observations and calculations. In Egypt, it is said, he acquired his opinions concerning the origin of the world, and learned the doctrines of the transmigration and immortality of the soul; but it is more probable, that he learned the latter doctrine from Socrates, and the former from Pythagoras. All things considered, it is not very likely that Plato derived his system of philosophy from the Egyptians; nor is it more probable, that during his residence in Egypt, Plato became acquainted with the doctrine of the Hebrews, and enriched his system with spoils from their sacred books.

The Platonic philosophy appears, in many respects, very consistent with the Mosaic; and a great party of the primitive fathers follow the opinions of that philosopher, as being favourable to Christianity. Justin is of opinion, that Plato could not learn many things which he has said in his works, from mere natural reason; but thinks he might have learnt them from the books of Moses, which he might have read when in Egypt.

Hence Numenius the Pythagorean expressly calls Plato the *Attic Moses*, and upbraids him with plagiarism; because he stole his doctrine about the world and God from the books of Moses.

Theodoret says expressly that he has nothing good and commendable about the Deity and his worship, but what he stole from the Hebrew theology; and Clemens Alexandrinus calls him the *Hebrew philosopher*.

Gale is very particular in his proof of the point, that Plato borrowed his philosophy from the scriptures, either immediately, or by means of tradition; and, beside the authority of the ancient writers, he brings some arguments from the thing itself. As, *e. gr.* Plato's confession, that the Greeks borrowed their knowledge of the one infinite God from an ancient people, better and nearer to God than they; by which people, our author makes no doubt, he meant the Jews, from his account of the state of innocence; as, that man was born of the earth, that he was naked, that he enjoyed a truly happy state, that he conversed with brutes, &c. In effect, from an examen of all the parts of Plato's philosophy, physical, metaphysical, and ethical, this author finds, in every one, evident characters of its sacred original.

St. Augustine commends the Platonic philosophy; and even says, that the Platonists were not far from Christianity. He adds, that the generality of the new Platonists of his time embraced the faith; and he expressly acknowledges, that

that it was by means of the Platonic system he was able to understand the doctrine of the Trinity.

Justin Martyr professes, that Plato's doctrine was of the utmost advantage to him, in helping him to believe the mysteries of the Christian faith. To which it may be added, that it was, in good measure, by Plato's help, that Origen confuted Celsus.

Indeed, the late author of "Platonisme Devoilé" carries things to an extravagant length, when he contends, that the dogmata of our religion are only the opinions of Plato; that the fathers give us nothing of the mysteries thereof, but what they learnt from him; and that Christianity is only Platonism veiled, or covered over. To which opinion, however, M. le Clerc seems also a little inclined.

The opinion, that Plato borrowed the dogmata of his philosophy from the scriptures, which has been strenuously maintained by several Jewish and Christian writers, has, however, as others maintain, little foundation besides mere conjecture; and it is supposed to have originated in that injudicious zeal for the honour of revelation, which led these writers to make the Hebrew scriptures, or traditions, the source of all gentile wisdom.

The chief grounds upon which the above-mentioned opinion rests are the following: 1. The authority of the Jewish writers, Josephus and Aristobulus, and of the Christian fathers, Justin Martyr, Clemens Alexandrinus, Eusebius, Cyril of Alexandria, Theodoret, Ambrose, and others. 2. The opinion that a Greek version of the Hebrew scriptures appeared in Egypt before the time of Plato, which he might have seen and read, as Clemens Alexandrinus and Eusebius, on the testimony of Aristobulus, assert. 3. The presumption, that the Egyptians borrowed many of their tenets from the Israelites, and communicated them to Plato. And, 4. The agreement of the doctrines of Plato with those of the Hebrews. But to these arguments it has been replied, 1. That the testimony of the Christian fathers is, with regard to the present question, of little value; as they had recourse to no authentic memorials or impartial witnesses, but credited the assertions of certain Jewish writers, who, several centuries after the time of Plato, with a view of gratifying their own vanity, and that of their countrymen, pretended that all gentile wisdom had been originally derived from Moses; and particularly, that Plato, during his residence in Egypt, had been instructed in the Hebrew school. This notion was eagerly adopted by several learned Platonists, who in the second century were converted to Christianity, but still retained an attachment to their former master; and from this time it became a common practice among those who affected the credit of Greek erudition, to maintain, that whatever opinions Plato and his followers held, similar to the doctrines of revelation, had been borrowed either from the Hebrews or Christians. 2. A Greek version of the Hebrew scriptures, prior to the time of Alexander, never existed but in the brain of Aristobulus. 3. Equally unsupported is the assertion, that the Egyptians, and even Plato himself, conversed with the Jews on theological subjects. Lastly, no proof of the point in question can arise from the supposed agreement between the Mosaic and Platonic doctrines; for the agreement is either imaginary, or it consists of such particulars as might be easily discovered by the light of reason. Besides, the true doctrine of Plato was so far adulterated and blended with other systems in the Alexandrian school, that those Christian fathers who had studied Platonism in this school, might easily conceive that there was a greater harmony between the Platonic doctrine and their own creed than in reality existed.

Plato, after having availed himself of all the information

which he could receive in distant countries, returned to the Pythagorean school at Tarentum, in Italy, and here he attempted to improve his own system by incorporating with it the doctrine of Pythagoras. In recounting the sources of Plato's philosophy, we may observe, that he borrowed his dialectics from Euclid of Megara; the principles of natural philosophy he learned in the Eleatic school, from Hermogenes and Cratylus; and combining these with the Pythagorean doctrine of natural causes, he framed from both his system of metaphysics. In mathematics and astronomy he was instructed in the Cyrenaic school, and by the Egyptian priests. From Socrates he imbibed the pure principles of moral and political wisdom, the simplicity of which he afterwards obscured by Pythagorean speculations. At length Plato, with his mind thus richly furnished, settled at Athens, and accomplished the design which he had long meditated, of forming a new school for the instruction of youth in the principles of philosophy. The place he chose for this purpose was a public grove, called the *Academy*; which see. Here he established his school, and over the door of it, in order to indicate his respect for mathematical studies, and how necessary a preparation he thought them for higher speculations, he placed this inscription, Οὐδεὶς ἀγνοούμενος εἰσέλθῃ: "Let no one, who is unacquainted with geometry, enter here." This school became famous, and was crowded not only by young men from every quarter and of every distinction, but by females disguised in men's clothes. Among the most illustrious of his followers we may reckon Dion, the Syracusan prince, and the orators Hyperides, Lycurgus, Demosthenes, and Isocrates.

Such distinguished reputation excited among the companions of Plato, formerly the disciples of Socrates, a spirit of emulation, which degenerated into envy, and which terminated in detraction and obloquy. To this natural jealousy it was owing, that Xenophon and Plato, though they relate the discourses of their common master, studiously avoid to mention one another. Diogenes the Cynic ridiculed Plato's doctrine of ideas, and other abstract speculations. Nevertheless, the fame of Plato increased, and his political wisdom was held in such high estimation, that several states solicited his assistance in new-modelling their respective forms of government. The Arcadians and the Thebans applied to him for this purpose, but he rejected their applications, because they refused to adopt the plan of his republic, which required an equal distribution of property. He gave his advice to several Grecian states, and furnished a code of laws for Syracuse. At three different periods he visited the court of Dionysius, tyrant of Sicily, and made several attempts to subdue his haughty and tyrannical spirit. The object of his first visit to Sicily, in the fortieth year of his age, was to survey the island, and to observe the wonderful phenomena of mount *Ætna*. During his residence at Syracuse, he was employed in the instruction of Dion, the king's brother-in-law; and in his efforts to rescue his pupil from the baneful influence of the general depravity, he was not disappointed. Dion, inspired with the love of wisdom, was desirous of introducing his preceptor to Dionysius, the tyrant; but his discourse with him being levelled against the vices and cruelties of his reign, the tyrant conceived a prejudice against Plato, and formed a design against his life, which by the assistance of Dion he escaped. Having engaged Pollis, a delegate from Sparta, to take charge of the philosopher, and to land him safely in his own country, Dionysius attempted to defeat his friendly purpose, and engaged Pollis either to put him to death, or to sell him as a slave, in his passage. Accordingly, Pollis sold him in the island of *Ægina*, the inhabitants of which were at war with the Athe-

PLATONISM.

nians. Here he became acquainted with Anicerris, a Cyrenaic philosopher, who testified his respect for Plato, by purchasing his freedom for thirty minæ, and sending him home to Athens; and when Plato's relations afterwards wished to repay the money which Anicerris had advanced, he declined accepting it, alleging, with the genuine spirit which true philosophy always inspires, that he saw no reason why Plato's relations should engross to themselves the honour of serving him.

After much solicitation and delusive promises on the part of Dionysius, Plato took a second journey to Syracuse, where he was received by the king with singular respect, and sacrifices were offered in congratulation of his arrival. It was not long, however, before Dion was banished into Italy, and Plato was sent back into his own country. Dionysius again renewed his intreaties for the return of Plato to his court, who arrived a third time at Syracuse, and for some time possessed the chief influence and authority there. But finding it impossible to prevail upon Dionysius to adopt his system of policy, or to recall Dion from his exile, a mutual distrust arose between the tyrant and the philosopher, and Plato, dissatisfied with his situation, earnestly requested permission to return to Greece. After some delay permission was granted, and a vessel of convoy was provided; but the tyrant again changed his mind, and detained Plato in Syracuse against his inclination. The tyrant's seeming respect was converted into rage, and the philosopher was dismissed from court, and committed to the custody of soldiers. When his Pythagorean friends at Tarentum heard of his dangerous situation, they dispatched an embassy to Dionysius, demanding a fulfilment of his promises; and the tyrant, dreading the consequences of a refusal, and the disgrace of having banished from his court the first philosopher of the age, gave Plato a magnificent entertainment, and sent him away loaded with rich presents.

Plato, returned to his country and his school, devoted himself to science, and spent the last years of a long life in the instruction of youth. Having enjoyed the advantage of an athletic constitution, and lived all his days temperately, he arrived at the 81st, or, according to some writers, the 79th year of his age, and died, through the mere decay of nature, in the first year of the 108th olympiad, B.C. 348.

He passed his whole life in a state of celibacy, and as he had no natural heirs, he bequeathed all his effects by will to his friend Adiantus. The grove and garden, which had been the scene of his philosophical labours, at last afforded him a sepulchre. Statues and altars were erected to his memory: the day of his death long continued to be celebrated as a festival by his followers; and his portrait is to this day preserved in gems: but the most permanent monuments of his genius are his writings, which have been transmitted, without material injury, to the present times.

The character of Plato has been differently appreciated. Whilst some have extolled him with the language of mere panegyric, as if he had been free even from human frailties, others have loaded his memory with unjust obloquy and reproach. Several anecdotes are preserved which reflect honour on his moral principles and character. Such was his command of temper, that whilst he was lifting up his hand to correct his servant for an offence, and perceiving himself angry, he kept his arm in that elevated posture, and said to a friend, who asked him what he was about to do, "I am punishing a passionate man." At another time, he said to one of his slaves, "I would chastise you if I were not angry." At the Olympic games he passed a day with some strangers, who were delighted with his affable conversation, and who merely knew that his name was Plato. When they parted,

he invited them, if they should visit Athens, to take up their residence at his house: they accepted his invitation, and were courteously entertained. During their stay, they expressed a wish to be introduced to his namesake, the famous philosopher, and to be shewn his academy. Plato, smiling, said, "I am the person you wish to see." The discovery surprized them, nor could they easily persuade themselves, that a philosopher, so eminent, would condescend to converse so familiarly with strangers. When he was informed that his enemies were industriously circulating reports to his disadvantage, he said, "I will live so, that none shall believe them." One of his friends remarking that he seemed no less desirous to learn himself, than to teach others, asked him, how long he intended to be a scholar? "As long," says he, "as I am not ashamed to grow wiser and better."

Of his merit as a philosopher, we may form the most satisfactory judgment from his writings. As to his style, it retained that strong tincture of a poetical spirit, which he discovered in his first productions. Hence have proceeded those encomiums which ancient and modern critics have passed upon his language; and on this account it was held in high estimation by Cicero, who says, that "if Jupiter were to speak in the Greek tongue, he would borrow the style of Plato." Aristotle describes it as "a middle species of diction, between verse and prose." Most of his dialogues, independently of the copious and splendid diction that enriches them, are justly admired for their literary merit: the introductions are pertinent and amusing; the course of the debate, or conversation, is clearly marked; the characters are accurately supported; every speaker has his proper place, language, and manner; the scenery of the conference is painted in lively colours; and the whole is, with admirable art, adorned and enlivened by those minute embellishments which render the colloquial mode of writing so peculiarly pleasing. Even upon abstract subjects, moral, metaphysical or mathematical, the language of Plato is often clear as the running stream, and in simplicity and sweetness vies with the humble violet which perfumes the vale. In these beautiful parts of his works, it has been conjectured, and not improbably, that Socrates and Lysias were his models. At other times, his style is turgid and bombast, puerile or frigid, and his metaphors are harsh, and he is too fond of introducing new terms, with a bold and unwarrantable innovation. Faults of this kind have been noticed and censured by several ancient critics. His conceptions also have been charged with an inequality, similar to that of his style. Whilst he adheres to the school of Socrates, and discourses upon moral topics, he is much more pleasing, than when he loses himself with Pythagoras, in abstruse speculations.

The Dialogues of Plato are classed by the ancients under the two heads of "didactic" and "inquisitive." The former are divided into "speculative," including *physical* and *logical*; and "practical," comprehending *ethical* and *political*. The latter, or "inquisitive," are characterised by terms taken from the athletic art, and divided into the "gymnastic," and the "agonistic;" those termed "gymnastic," supposed to be similar to the *exercise*, were subdivided into the *majestic*, as resembling the teaching of the rudiments of the art, and the *picarastic*, as represented by a skirmish, or trial of proficiency. The "agonistic" dialogues, supposed to resemble the *combat*, were either *endeistic*, as exhibiting a specimen of skill, or *anatriptic*, presenting the spectacle of a perfect defeat. Instead of this whimsical classification, Plato's dialogues may not improperly be divided into *physical*, *logical*, *ethical*, and *political*.

The writings of Plato were originally collected by Hermodorus, one of his pupils: they consist of 35 dialogues, and 13 epistles. They were first published, after the invention of printing, by Aldus Manutius, at Venice, in 1513. The editions of Ficinus and Serranus are the most valuable; but the notes and interpretations should be read with caution; for Ficinus, having formed his conceptions of the doctrine of Plato after the model of the Alexandrian school, frequently, in his "Arguments," misrepresents the design of the author, and in his version obscures the sense of the original; and Serranus, for want of an accurate acquaintance with the doctrine of his author, and under the influence of a strong predilection for the scholastic system of theology, sometimes gives an incorrect and injudicious explanation of the text.

Availing ourselves of the excellent work, which has furnished the materials of this article, we shall now proceed to detail the philosophical system of Plato, in order to which some general observations should be premised. Plato, disdainful of the sober method of reasoning introduced by Socrates, left his first master in search of other preceptors. Inclined to speculative refinement, and misled by the celebrity of the Italian school, which abounded in subtleties, he attached himself to the Pythagorean philosophy; and pursuing his studies under the Egyptian priests, he deviated still farther from the plain path of common sense, which had been pursued in the Socratic school. Among other errors which he adopted from foreign philosophy, it was not the least that he borrowed the art of concealing his real opinions: and hence his writings became not only incidentally, but perhaps designedly, obscure. After the example of Pythagoras, he threw a veil of obscurity over his public instructions, which was removed only for the benefit of those who were admitted to his more private and confidential lectures. This concealed method of philosophizing he adopted partly from a regard to his personal safety, and partly, if not principally, from motives of vanity. For this purpose the colloquial form of instruction, introduced by Socrates in his contests with the Sophists, and adopted in the Dialectic schools, was found by Plato to be peculiarly convenient. Accordingly Cicero, though an enthusiastic admirer of Plato, observes, that "Plato affirms nothing, but after producing many arguments, and examining a question on every side, leaves it undetermined." His language likewise, occasionally splendid, and at other times ambiguous and equivocal, renders his meaning often doubtful and unintelligible: to which we may add, that the obscurity of his writings is greatly increased by the intermixture of mathematical ideas or language with those of metaphysics. After all, the principal cause of the want of perspicuity that characterizes the writings of Plato is the extreme subtlety of his speculations upon abstract and sublime topics. Raising man above his condition and nature, Plato unites him to certain imaginary divine principles, leads him through various orders of emanation and forms of intelligence to the Supreme Being, and represents these fictions of fancy as the first principles of wisdom. In such a wondrous maze of words does Plato involve his notions, that none of his disciples, not even the sagacious Stagirite, could unfold them; and yet we receive them as sacred mysteries, and if we do not perfectly comprehend them, imagine that our intellects are too feeble to penetrate the conceptions of this divine philosopher, and that our eyes are blinded, as Burnet in his "Archæologia" expresses it, by that resplendent blaze of truth, upon which his eagle sight could gaze without injury. Plato, indeed, ambitious of the honour of forming a new sect, and endued by nature with more bril-

liancy of fancy than strength of judgment, collected the tenets of other philosophers, which were, in many particulars, contradictory, and could by no exertion of ingenuity be brought to coalesce; and that, out of this heterogeneous mass, he formed a confused system, destitute of form or consistency. This, it is said, will be acknowledged by every one, who, in perusing the philosophical writings of Plato, is capable of divesting himself of that blind respect for antiquity, by which the learned so frequently suffer themselves to be misled. In confirmation of this judgment, we need only refer to the dialogue entitled "Timæus;" a chaotic mass of opinions, which no commentators have yet been able to reconcile, or to explain. The followers of Plato, instead of arising to disperse the clouds that envelope his system, seem to have combined in increasing its obscurity. By successive changes in the academy, after the death of its founder, new opinions were introduced, and these increased the difficulty of exploring the true sense of Plato; and when, in a subsequent period, the Platonic philosophy was professed in Alexandria, it was further adulterated by an injudicious and absurd attempt to mould into one system the doctrines of Plato, the traditional tenets of Egypt and the eastern nations, and the sacred records of the Jews and Christians; a coalition which will appear, in the sequel of this article, to have proved exceedingly injurious both to philosophy and religion.

All the preceding circumstances considered, it will appear to be no easy task to delineate an accurate sketch of the Platonic philosophy. This philosophy, as he suggests, and his interpreters allow, may be divided into three branches: the first treating of the art of reasoning, or dialectics; the second, of theoretical questions concerning nature, or physics; and the third, of practical subjects respecting life and manners, or ethics.

Wisdom, in the strict Platonic sense of the term, is the knowledge of those things which truly exist, and are comprehended by the intellect, particularly those which respect God, and the human soul as distinct from the body. Philosophy is the desire of divine science, or the liberation of the mind from the body, and its direction towards those real essences, which are perceptible only by the understanding: accordingly, a philosopher must possess a mind naturally turned towards contemplation, an ardent love of truth, a penetrating judgment, and a retentive memory; and he must also be inured to the exercise of temperance and fortitude, that nothing corporeal may divert him from the pursuit of wisdom. Philosophy, as employed in the contemplation of truth, is termed theoretical; and as conversant in the regulation of actions, it is practical. The former produces a contemplative life, in which the mind, occupied in meditations purely intellectual, acquires a resemblance to the divinity; the latter leads to an active life, and applies the principles of wisdom to the benefit of society. Besides the contemplation of truth and virtue, the philosopher will inquire into the right conduct of the understanding, and the powers of speech in the pursuits of knowledge, or will study the art of reasoning or disputation. The office of philosophy then is threefold, *dialectic, theoretical, and practical.*

For the sum of Plato's doctrine on *dialectics*, as collected from his dialogues, see *DIALECTICA*. The *theoretical* philosophy is divided by Plato into three branches, *viz. theological, physical, and mathematical.*

On *theology*, the fundamental doctrine of Plato, as well as that of other ancient philosophers, is, that from nothing nothing can proceed. This universal axiom, applied not only to the infinite efficient, but to the material cause,

Plato,

Plato, in his "Timæus," lays down as the ground of his reasoning concerning the origin of the world. In this dialogue, which comprehends his whole doctrine on the formation of the universe, matter is so manifestly spoken of as eternally co-existing with God, that this part of his doctrine could not have been mistaken by so many learned and able writers, if they had not been desirous of establishing a coincidence of doctrine between the writings of Plato and of Moses. On the other hand, it is observed by the learned Dr. Cudworth, that though some of the ancient fathers impute to Plato the opinion, that matter was an unmade self-existent being, there seems to be no sufficient ground for their so doing; and Porphyry, Iamblichus, Proclus, and other Platonists, do not only professedly oppose the same as false, but also as that which was dissonant from Plato's principles. However, he acknowledges, that Plato did assert a plurality of gods, meaning animated or intellectual beings, or dæmons, superior to men, to whom honour and worship are due, and applying the appellation to the sun, moon, and stars, and also to the earth. Nevertheless he asserts, at the same time, that there was one supreme God, the self-originated being, the maker of the heaven and earth, and of all those other gods. He also maintains, that the Psyche, or universal mundane soul, which is a self-moving principle, and the immediate cause of all the motion which is in the world, was neither eternal nor self-existent, but made or produced by God in time; and above this self-moving Psyche, but subordinate to the Supreme Being, and derived by emanation from him, which he calls *τὸ θεῖον*, and *τὸ εὐδαιμόνιον*, the good, he supposes an immovable Nous or intellect, which was properly the Demiurgus, or former of the world.

The first matter of which this body of the universe was formed, he observes, was a rude undigested heap, or chaos: now, adds he, the creation was a mixed production; and the world is the result of a combination of necessity and understanding, *i. e.* of matter, which he calls necessity, and the divine wisdom; yet so that mind doth rule over necessity: and to this necessity he ascribes the introduction and prevalence both of moral and natural evil; maintaining, however, that the evils resulting from the necessity of imperfect beings are over-ruled by Mind or God for good.

The principles, or elements which Plato lays down are fire, air, water, and earth.

He supposes two heavens, the *empyrcan*, which he takes to be of a fiery nature, and to be inhabited by angels, &c.; and the *starry* heaven, which he teaches is not adamantine, or solid, but liquid and spirable.

Although Plato, in his "Timæus," as other writers argue, calls God "the parent of the universe;" and in his "Sophista," speaks of him as "creating animate and inanimate beings, which did not before exist;" yet these expressions do not necessarily imply that no prior matter existed, from which these new beings were formed. Through the whole "Timæus," Plato supposes two eternal and independent causes of all things: one, that by which all things are made, which is God; the other, that from which all things are made, which is matter. He distinguishes between God, matter, and the universe; and supposes the architect of the world to have formed it out of a mass of pre-existent matter. According to Plato, matter is an eternal and infinite principle, originally of no form, yet capable of receiving any, and infinitely divisible; but his notion of it is essentially different from that which supposes it to consist of small indivisible particles; and, therefore, Plato is not to be ranked among the Atomic philosophers. Plato also maintains, that there is in matter a necessary, but

blind and refractory force; and that hence arises a propensity in matter to disorder and deformity, which is the cause of all the imperfection which appears in the works of God, and the origin of evil. See *EVIL*.

The principle opposite to matter, in the system of Plato, is God, an intelligent cause, the origin of all spiritual being, and the former of the material world; whose nature he thought it difficult to discover, and, when discovered, impossible to divulge. The existence of God he inferred from the marks of intelligence, which appear in the form and arrangement of bodies in the visible world; and from the unity of the material system he concluded, that the mind by which it was formed must be one. God, according to Plato, is the supreme intelligence, incorporeal, without beginning, end, or change, and capable of being perceived only by the mind. Plato ascribes to the Deity all those qualities which modern philosophers attribute to immaterial substance, and conceives him to be in his nature simple, un-circumscribed in space, the author of all regulated motion, and, in fine, possessed of intelligence in the highest perfection. Whatever were Plato's notions of the essence of Deity, he ascribed to him wisdom and power sufficient for the formation and preservation of the world; and supposed him possessed of goodness, which inclined him to desire, and, as far as the refractory nature of matter would permit, to produce, the happiness of the universe. This great being is distinguished by the appellation *Τὸ Ἀγαθόν*, the Good. "God, that he might form a perfect world," says Plato, followed that eternal pattern, which remains immutable, and which can only be comprehended by reason." But this pattern, or archetype, he has explained so obscurely, that his interpreters and followers have been led to adopt very different opinions concerning it. Some have inferred from various passages that occur in his writings, that the whole of Plato's doctrine, with respect to the formation of the world, amounts to nothing more than that the Deity employed his understanding or reason in planning and executing the system of the universe; and, consequently, that by ideas existing in the reason of God are only meant conceptions formed in the divine mind. But by ideas Plato appears to have meant something much more mysterious; namely, patterns, or archetypes, subsisting by themselves, as real beings, *ἰδέαι ὁραταί*, in the divine reason, as in their original and eternal region, and issuing thence to give form to sensible things, and to become objects of contemplation and science to rational beings. It is the doctrine of the "Timæus," that *ὁ λογισμὸς τοῦ θεοῦ*, the reason of God, comprehends examples of all things, and that this reason is one of the primary causes of things. Plutarch says, that Plato supposes these principles God, matter, and idea. Justin Martyr, Pseudo-Origen, and others, assert the same. These ideas Plato defines to be the peculiar natures of things, or essences as such; and asserts, that they always remain the same, without beginning or end. Plato, having been from his youth conversant with Cratylus, a disciple of Heraclitus, and instructed in the doctrine of that school, that all sensible things are variable, and cannot be proper objects of science, reasonably concluded, that if there be any such thing as science, there must exist, besides sensible objects, certain permanent natures, perceptible only by the intellect. Such natures, divine in their origin, and eternal and immutable in their existence, he admitted into his system, and called them ideas. These objects of contemplation and science Plato seems to have found in the school of Pythagoras, whose numbers agreed in many leading characters with the ideas of Plato, and were employed for the same purposes, namely, to furnish objects of true science, and to elevate the human mind

mind to a resemblance to the divine. Plato compares the state of the human mind, with respect to the material and the intellectual world, to that of a man, who, in a cave into which no light can enter but by a single passage, views, upon a wall opposite to the entrance, the shadows of external objects, and mistakes them for realities. See the article PERCEPTION.

It was another doctrine in the Platonic system, that the deity formed the material world after a perfect archetype, which had eternally subsisted in his reason, and endued it with a soul. This Plato supposed to be the animating principle in the universe, pervading and adorning all things. This third principle in nature is, in the Platonic system, inferior to the Deity, being derived from that divine reason, which is the seat of the ideal world; thus essentially differing from the Stoical doctrine of the soul of the world, which supposed the essence of the divine nature diffused through the universe. The doctrine of a twofold soul of the world, the one *πρεξουσιον*, presiding over it, the other *εγκουσιον*, residing in it, is an appendage to the ancient Platonic system, introduced by the later Platonists, to accommodate this system to the notions adopted by many of the Christian fathers concerning the divine nature. But Plato's doctrine concerning God and the soul of the world differs materially from the doctrine of the Trinity, afterwards received in the Christian church. Plato did not suppose three substances in one divine essence, separate from the visible world; but he taught, that the *λογος*, or reason of God, is the seat of the intelligible world, or of ideas, and that the soul of the world is a third subordinate nature, compounded of intelligence and matter. In the language of Plato, the universe, being animated by a soul which proceeds from God, is the son of God; and several parts of nature, particularly the heavenly bodies, are Gods. He probably conceived many subordinate divinities to have been produced at the same time with the soul of the world, and imagined that the Supreme Being appointed them to the charge of forming animal bodies, and superintending the visible world; a doctrine which he seems to have borrowed from the Pythagoreans, and particularly from Timæus the Locrian, who says, "the ruler of all assigned the inspection of human affairs to demons, and committed to them the government of the world."

On the foundation of the doctrine, above explained, concerning God, matter, ideas, the soul of the world, and demons, Plato raised the structure of his physics: thinking, that the supreme Architect, by uniting eternal and immutable ideas or forms to variable matter, produced the visible world; and believing, that the world had a beginning in time, and not to have existed from eternity.

Other tenets included in the Platonic doctrine of nature were, that the universe is one animated being, including within its limits all animated natures; that fire and earth were first formed, and afterwards united by means of air and water; that from perfect parts one perfect whole was produced, of a spherical figure, as in itself most beautiful, and best adapted to contain all other figures; that the elementary parts of the world are of regular geometrical forms, the particles of earth being cubical, those of fire pyramidal, those of air in the form of an octahedron, and those of water in that of an icosaedron; that these are adjusted, in number, measure, and power, in perfect conformity to the geometrical laws of proportion; that the soul which pervades this sphere is the cause of its revolution round its centre; and, lastly, that the world will remain for ever, but that, by the action of its animating principle, it accomplishes certain periods, within which every thing returns to

its ancient place and state. This periodical revolution of nature is called the PLATONIC, or *Great year*.

Plato's doctrine concerning the human soul, as an emanation from God, is treated obscurely. This emanation was not immediate, but through the intervention of the soul of the world, debased by some material admixture; and consequently the human soul, receding farther from the first intelligence, is inferior in perfection to the soul of the world. The human soul, in the material part of its nature, is formed for conversing with sensible objects, and, in its intellectual part, capable of spiritual contemplation; but what he meant by *οχημα*, the material vehicle of the soul, is uncertain. The relation which the human soul, in its original constitution, bears to matter, Plato appears to have considered as the source of moral evil. As to the manner in which the soul acts on the body, Plato speaks obscurely and inconsistently; but it is probable, that, as he conceived the soul of the world to produce the motion of the earth, and the heavenly bodies, by means of that part of its nature which is material; so he supposed the power of moving bodies, which belongs to the human soul, to be the effect of its material principles. With regard to the origin and present state of human souls, Plato supposes, that when God formed the universe, he separated from the soul of the world inferior souls, equal in number to the stars, and assigned to each its proper celestial abode; but that these souls, by some means, or for some reason or other not explained, were sent down to the earth into human bodies, as into a sepulchre or prison; and to this cause he ascribes the depravity and misery to which human nature is liable; maintaining, at the same time, that by disengaging itself from all animal passions, and rising above sensible objects to the contemplation of the world of intelligence, the soul of man can be prepared to return to its original habitation. According to Plato, the soul consists of three parts, *viz.* the seat of intelligence, that of passion, and that of appetite; and he assigns to each its proper place in the human body. The first of these portions or faculties of the soul, under both which denominations he speaks of them, he conceived to have been derived from God; the second and third from matter. Plato teaches, in express terms, the doctrine of the immortality of the rational soul, resting the proof of this doctrine, however, upon arguments drawn from the mere fanciful parts of his system.

Plato was a zealous advocate for the importance of that kind of science, which is purely speculative, and though he has left no direct treatise on mathematics, he requires from his disciples an acquaintance with the elements of this branch of knowledge, preparatory to the study of theoretical philosophy. On the subjects of policy and morals he prescribes rules, which are intended for the direction of societies and individuals in the offices of life, but they are too much tinged with his theoretical doctrines. The main object of his political institutions, appears to have been the subjugation of the appetites and passions, by means of the abstract contemplation of ideas. The chief heads of his moral doctrine are as follow: Our highest good consists in the knowledge and contemplation of the first good, which is mind, or God. All those things which are called good by men, are really such only so far as they are derived from the first and highest good. The only power in human nature, which can acquire a resemblance to the Supreme good, is reason. The minds of philosophers are fraught with valuable treasures; and, after the death of the body, they shall be admitted to divine entertainments; so that whilst with the gods they are employed in surveying the fields of truth, they will look down with contempt on the folly of those, who are con-

tented

tened with earthly shadows. Goodness and beauty consist in the knowledge of the first good, and the first fair. That only which is becoming is good; therefore virtue is to be preferred for its own sake; and, because it is a divine attainment, it cannot be taught, but it is the gift of God. He alone, who has attained the knowledge of the first good, is happy; the end of this knowledge is, to render man as like to God as the condition of human nature will permit. This likeness consists in prudence, justice, sanctity, temperance. In order to attain this state, it is necessary to be convinced, that the body is a prison, from which the soul must be released, before it can arrive at the knowledge of those things which are real and immutable. Virtue is the most perfect habit of mind which adorns the man, and renders him firm, resolute, and consistent, in action and speech, in solitude and society. The virtues are so nearly allied, that they cannot be separated: they are perfect, and therefore neither capable of increase, nor of diminution. The passions are motions of the soul, excited by some apparent good or evil: they originate in the irrational parts of the soul, and must be regulated and subdued by reason. Friendship is, strictly speaking, reciprocal benevolence, which inclines each party to be as solicitous for the welfare of the other, as for his own. This equality of affection is created and preserved by a similarity of disposition and manners. Upon the whole it may be observed, that whilst the writings of Plato contain many just and sublime sentiments on moral subjects, his ethical doctrine, duly examined, will appear to be, in some particulars, defective, and in others extravagant and absurd. The fanciful notions which he entertained concerning the divine nature, the world of ideas, and matter, seem to have given a romantic and enthusiastic turn to his conceptions on morals; a defect, which may be in part ascribed to his connection with the Pythagorean school, but which was, perhaps, chiefly owing to the peculiar propensity of his genius towards metaphysical fiction.

After the death of Plato, two of his principal disciples, Aristotle and Xenocrates, continuing his office, and teaching, the one in the ACADEMY, and the other in the LYCÆUM, founded two sects, under different names, though in other respects the same; the one retaining the denomination of ACADEMICS, the other assuming that of PERIPATETICS. The Academic sect fell into general neglect under the Roman emperors; partly because it was treated with contempt by the dogmatists, and partly on account of the reviving credit of the Sceptic sect, in which the peculiar tenets of the Middle Academy were embraced. Nevertheless, the true doctrine of Plato, which had formerly obtained such high esteem among philosophers, and which had been lately restored at Athens by Antiochus, resumed its honours. Among the genuine followers of Plato, we find, at this period, several illustrious names. Under the emperors Augustus and Tiberius, flourished Thrasybulus, a Mendesian, who, though an eminent Platonist, so far conformed to the practice of the Pythagoreans, as to become an adept in the art of astrology. Not long after his time lived Theon of Smyrna; to whose astronomical observations, Ptolemy the astronomer, who flourished under Antoninus Pius, has referred, and whose mathematical treatises, elucidating the writings of Plato, prove that he belonged to the Platonic school. At the same time, his discourses in geometry, arithmetic, music, astronomy, and the harmony of the universe, serve to cast some light upon the Pythagorean system. Alcinous, whose age is uncertain, but commonly placed about the beginning of the second century, wrote an introduction to Plato, containing a summary of his doctrine, which shews him to have been well acquainted with his phi-

losophy. Favorinus, a native of Arles, lived in the reigns of Trajan and Adrian, and was well instructed in the precepts of philosophy by Epictetus, the illustrious ornament of the Stoical school; but none of his writings are extant. Under the reign of Antoninus Pius flourished Calvisius Taurus of Beryta, and he is mentioned as a Platonist of some note. He wrote several pieces, chiefly to illustrate the Platonic philosophy; he lived at Athens, and taught, not in the schools, but at his table. Aulus Gellius was frequently one of his guests, and in his "Noctes Atticæ" has given an account of the manner in which these philosophical entertainments were conducted. The same period produced Lucius Apuleius; see his article. Another Platonist, who flourished under M. Aurelius Antoninus, was Atticus; chiefly memorable for the laudable pains with which he endeavoured to ascertain the exact points of difference between the doctrines of Plato and Aristotle. (See ATTICUS.) Numenius of Apamea in Syria belonged to the same class of writers with Atticus; and Maximus Tyrius, though chiefly distinguished by his eloquence, obtained some degree of celebrity as a philosopher; and his elegant Dissertations are for the most part written upon Platonic principles, though they sometimes incline towards scepticism. Plutarch and Galen are also commonly ranked among the Platonists. See their respective articles.

In later times, about the first ages of the Christian church, the followers of Plato abandoned the title of "Academics" or "Academists," and assumed that of "Platonists." It is supposed to have been at Alexandria, in Egypt, that they first assumed their new title, after having restored the ancient Academy, and re-established Plato's sentiments; many of which, in process of time, had been laid aside. Among the Greek Platonists, those who acquired the greatest reputation were Porphyry, Plotin, Iamblichus, Proclus, and Plutarch; and among the Latins, Apuleius and Chalcidius. Among the Hebrews, Philo Judæus occupied the chief rank. The modern Platonists were Plotin, the founder, at least the reformer of their sect.

It is certain, that most of the celebrated fathers were Platonists, and borrowed many of their explanations of scripture from the Platonic system. In order to account for this fact, we may observe, that, towards the conclusion of the second century, a new sect of philosophers, called the modern, or later Platonics, arose of a sudden, spread with amazing rapidity through the greatest part of the Roman empire, swallowed up almost all the other sects, and proved extremely detrimental to Christianity. The school of Alexandria in Egypt, instituted by Ptolemy Philadelphus, renewed and reformed the Platonic philosophy. The votaries of this system distinguished themselves by the title of Platonics, because they thought that the sentiments of Plato, concerning that most noble part of philosophy, which has the Deity and things invisible for its objects, were much more rational and sublime than those of the other philosophers. This new species of Platonism was embraced by such of the Alexandrian Christians as were desirous to retain, with the profession of the Gospel, the title, the dignity, and the habit of philosophers.

Those Alexandrian philosophers, who became converts to the Christian faith, retained a strong predilection for Platonic tenets, and the highest reverence for the name of Plato; and therefore they easily credited the report, that the doctrine of Plato concerning the divine nature had been derived from revelation; and hence they thought themselves justified in attempting a coalition between Plato and Jesus Christ. An union of Platonic and Christian doctrines was unques-

commendations which he bestows upon Porphyry, as the best interpreter of Aristotle, he seems to have united the Platonic with the Aristotelian doctrine. Æneas Gaza, towards the close of the fifth century, in a poem professedly written against the Platonists, confounds the doctrines of Platonism and Christianity. Under the emperor Justinian, who issued a particular edict, prohibiting the teaching of philosophy at Athens, which edict seems to have been levelled at modern Platonism, all the celebrated philosophers of this sect took refuge among the Persians, who were, at that time, the enemies of Rome; and though they returned from their voluntary exile when the peace was concluded between the Persians and Romans, A.D. 533, they could never recover their former credit, nor obtain the direction of the public schools. Thus, says Mosheim, expired that famous sect, which was distinguished by the title of the modern or later Platonists, and which, for a series of ages, had produced such divisions and tumults in the Christian church, and which had been, in other respects, prejudicial to the interests and progress of the Gospel. For a farther account of this sect, see *ELECTICS*.

The knowledge of Alexandrian Platonism was, however, revived in the West by Joannes Scotus, who, in the ninth century, translated the books ascribed to Dionysius the Areopagite, or St. Denys, and laid the foundation of the mystical system of theology, which afterwards so generally prevailed. Thus philosophical enthusiasm, born in the East, nourished by Plato, educated in Alexandria, matured in Asia, and adopted into the Greek church, found its way, under the pretext and authority of an apostolic name, into the western church, and there produced innumerable mischiefs.

The first Greek who gave occasion to the revival of Platonism in Italy, was Gemistius Pletho, a native of Constantinople, who was born in 1390, and lived 100 years. He was a zealous advocate for Platonism, and maintained a violent controversy with the Aristotelians. In his "Expositio Oraculorum Magicorum Zoroastris," he exhibits twelve fundamental articles of the Platonic religion, and gives an elegant compendium of the whole Platonic philosophy. A more moderate adherent to Plato, who maintained his system without casting contempt on the philosophy of Aristotle, or trespassing upon the doctrine of Christianity, was Bessarion, a learned bishop of Nice, who was appointed by the emperor Michael Palæologus, about the year 1440, together with other Greek divines, to treat with the Latin church concerning an union. He died at Ravenna in 1472. He wrote a defence of the Platonic system against George of Trebizond. Under the patronage of Cosmo de Medici, Marsilius Ficinus, a Florentine, born in 1433, was educated by Pletho, for the express purpose of translating the writings of Plato. It appears, however, from the execution of the task assigned him, and his other writings, that he was deficient in strength of judgment and correctness of taste. His Latin style wants that richness and dignity which are requisite in a version of Plato. A fellow labourer with Ficinus, in the task of editing and translating the writings of Plato, was Joannes Picus of Mirandola, born in 1460; who, for his success in reviving the Platonic philosophy, was honoured with the title of the phoenix of his age. Picus was a zealous supporter of Platonism, after the model of the Alexandrian school; but not without blending with its doctrine a large portion of Cabbalistic mystery, and confounding with both these the doctrine of divine revelation. About this period, a body of Greek scholars avowed themselves zealous advocates for the genuine Aristotelian philosophy; and employed their time and learning in editing and translating the

writings of the Stagirite. The principal of those who laboured in this undertaking were Theodore Gaza, George of Trebizond, and Georgius Scholarius. Between these philosophers, on the one part, who followed Plato, and those on the other who followed Aristotle, a dispute arose concerning the merit and authority of their respective masters, which was carried on to a most ridiculous and extravagant height. It was begun by Pletho, whose veneration for Plato led him to oppose with great violence the unrivalled dominion which Aristotle had for ages possessed in the schools. Georgius Scholarius, on the other hand, zealously defended Aristotle, and strenuously maintained that his opinions are consonant to the truest and best doctrines of the Christian religion, and are *even more true*; and that the tenets of Plato, differing from those of Aristotle, are *therefore false*. George of Trebizond supported Scholarius; and Pletho was ably seconded by Gaza. Other combatants also engaged in the contest, and in the prosecution of it exposed themselves to ridicule. The partisans of the Platonic system, who, under the patronage of the Medicean family, for a long time maintained their ground against the Aristotelians, declining with the fortune of their patrons, the advocates for the Peripatetic philosophy proportionably increased, and after a violent struggle, established a victory.

The doctrines of the later Platonists having been revived by the Greek exiles in Italy, their farther spread is chiefly to be imputed to the aversion which many good men entertained against the Peripatetic philosophy, on account of the shameful impieties to which it had given birth. Perceiving that they could not commit themselves to the direction of Aristotle, without hazarding their religious principles; and not having strength of mind sufficient to form a system of opinions for themselves, they adopted the philosophy of Plato in the corrupted state in which it had been transmitted, through the Alexandrian and Christian schools, to modern times. This philosophy was the more readily embraced, because it was believed, that the mysteries of Pythagoras, than which none appeared to approach nearer to those of true religion, had been long since united with the wisdom of Plato. In this school they expected to find much divine instruction; more especially as they were led to believe, that its doctrines had been, mediately or remotely, derived from divine revelation. And as one error generally produces another, these learned men united with this system the secret or cabbalistic philosophy of the Jews, which, for want of due examination, they conceived to have been the pure doctrine of the ancient Hebrews. Hence arose a new compound of tenets, sufficiently mysterious and paradoxical, which was received by this class of philosophers as the sum of ancient wisdom. Whilst Ficinus was reviving the Platonic philosophy in Italy, and Faber the Aristotelian in France, John Reuchlin, otherwise called Capnio, born at Pforzheim, in Suabia, in 1455, professed and taught a mystical system, compounded of Platonic, Pythagoric, and Cabbalistic doctrines. George Venet, an obscure and enthusiastic writer, pursued a similar course, and blended sundry Peripatetic notions with the Platonic and Cabbalistic systems. The mystic system of Cabbalistic Platonism was ably supported by Henry Cornelius Agrippa. A very different mode of restoring the Platonic philosophy was pursued by Franciscus Patricius, born at Clissa, in Illyricum, in 1529. In the schools of Italy he professed to unite the doctrines of Aristotle and Plato, but in reality undervalued that of the former. Being appointed by pope Clement VIII. a preceptor in philosophy at Rome, he openly discovered his aversion to the Aristotelian system, and advised the pope to prohibit the teaching of this philosophy in the schools, and to introduce the doctrine of Plato, as more

consonant to the Christian faith. In the 17th century, Platonism found many advocates in Great Britain, owing, in a great measure, to the desire which many able and learned divines at this time entertained of refuting the tenets of Hobbes; and this they thought could not be more effectually done, than by reviving an attention to the doctrine of Plato, both in his own works, and in those of his followers. Of those who ranged themselves under the banners of Plato, the most celebrated are Gale, Cudworth, and More. Brucker's History of Philosophy, by Enfield, vol. i. and ii. Mosheim's Eccl. Hist.

PLATONISTS. See **PLATONISM** and **ACADEMICS**.

PLATONOPOLIS, in *Ancient Geography*, a city which Plotinus requested the emperor Galienus to build in Campania. This city had been formerly razed, and Plotinus used his interest with the emperor, not only to have it rebuilt, but to obtain a grant of the neighbouring territory, that it might be inhabited by a body of philosophers, and governed by the laws of Plato, under the name of Platonopolis. He promised, at the same time, that he and his friends would lay the foundation of this philosophical colony. The emperor was dissuaded by his friends from acceding to this proposal.

PLATOON, or **PLOTTOON**, formed, by corruption, of the French *pelaton*, a bottom, or clue, of thread, in War, formerly denoted a small body of men, drawn out of a battalion of foot, and placed between the squadrons of horse, to sustain them; or in ambuscades, straits, and defiles, where there is not room for whole battalions or regiments.

Platoons were also used when they formed the hollow square, to strengthen the angles.

The grenadiers were generally posted in platoons.

A battalion was generally divided into sixteen platoons, exclusive of the grenadiers, which formed two or four platoons more, as occasion required. At present the battalion is generally divided into wings, grand divisions, divisions (or companies), subdivisions, and sections; and the word platoon is seldom used, except to denote a number (from 10 to 20) of recruits assembled for the purpose of instruction, in which case it may be considered as synonymous with company. See **BATTALION**.

PLATOON Exercise. See **BATTALION**.

PLATOON Firing. See **BATTALION** and **FIRING**.

PLATOON Pivots. See **PIVOT**.

PLATTE, or *Shallow River*, in *Geography*, a western branch of the river Missouri, remarkable for its quicksands and bad navigation. Near the confluence of this river with the Missouri, dwells the nation of the Octolactos, or Otos, consisting of about 200 warriors.

PLATTE, *La*, a smaller river of America, in the state of Vermont, which runs into lake Champlain, at Shelburn.

PLATTE Forme, *La*, a cape on the W. coast of St. Domingo. N. lat. 19° 36'. W. long. 74° 2'.—Also, a town on the S. side of the N. peninsula of St. Domingo; 13 leagues S.E. by S. of the Mole.

PLATTEN, a town of Bohemia, in the circle of Leitmeritz; 4 miles E. of Kamnitz.—Also, a town of Bohemia, in the circle of Elnbogen; 27 miles N.E. of Eger. N. lat. 50° 23'. E. long. 12° 45'.

PLATTENBURG, a citadel of Brandenburg, in the Mark of Pregnitz; 4 miles E. of Wilfnach.

PLATTS, a small island in the Indian sea. S. lat. 5° 55'. E. long. 55° 20'.

PLATTS, on board a *Ship*. See **PLATS**.

PLATTSBURG, in *Geography*, a post-town of America, in Clinton county, New York, on lake Champlain; 5 miles W. of Ticonderoga. N. lat. 44° 41'. W. long.

73° 27'. Here are a house for public worship, a court-house, and a gaol. The court of common pleas and grand sessions of the peace sit here twice a-year; and in the town are artizans of almost every kind, who furnish among themselves all the materials for building, glass excepted. Here also be found polite circles. The number of inhabitants is 1409.

PLATUNIUM, in *Botany*, from *πλατύνω*, to dilate or enlarge, in allusion to its large spreading calyx; a genus described by Jussieu, in the *Annales du Musée*, v. 7. 65, with which we are unacquainted. *De Théis*. 371.

PLATYCEROS OVIS, in *Zoology*, the name given by Gesner and some others to a species of sheep, commonly called *ovis laticauda*, or the broad-tailed sheep. See **OVIS**.

PLATYCEROS is also a name given by Pliny to the **CERVUS Dama**, or fallow deer.

PLATYCEROS, in *Entomology*, a species of *Lucanus*. See **LUCANUS Alces**, and **LUCANUS parallelepipedus**. See also **TENEBRIO Caraboides**.

PLATYLOBIUM, in *Botany, so named, by the writer of the present article, from *πλατύς*, broad, and *λοβός*, a pod or legume; because of the breadth of that part, which is further augmented by a dilatation, or wing, running along the back.—Sm. Tr. of Linn. Soc. v. 2. 350. v. 9. 302. Bot. of New Holl. 17. Willd. Sp. Pl. v. 3. 921. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 4. 266.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, two-lipped; the upper lip rounded, very large, divided half way down into two obovate segments; the under much smaller, in three equal, awl-shaped, straight segments. *Cor.* papilionaceous. Standard heart-shaped, large, ascending, twice as long as the upper lip of the calyx, with a shortish, linear, convex claw. Wings half the length of the standard, obovate, each with a plait, and prominent tooth, at the base on its lower side, and a narrow claw. Keel the length of the wings, of two obovate, concave, converging petals, each with a tooth on its upper edge at the base. *Stam.* Filaments ten, united into one set for about half their length, separate only at the upper edge, ascending; anthers simple, roundish. *Pistl.* Germen on a short stalk, oblong, compressed; style recurved; stigma simple. *Peric.* Legume stalked, oblong, compressed, almost flat, of one cell, its upper edge dilated into a flat longitudinal wing, the valves membranous. *Seeds* several, oval, compressed, each on a curved white stalk, with a tumid appendage.

Ess. Ch. Calyx two-lipped; the upper lip cloven, rounded, very large. Stamens all connected. Legume stalked, compressed flat, membranous, winged at the back, of one cell, with many seeds.

1. *P. formosum*. Orange Flat-pea. Sm. Bot. of New Holl. 17. t. 6. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 469. Venten. Malmaif. t. 31.—Leaves ovate, somewhat heart-shaped. Germen all over hairy. Stalk of the legume shorter than the calyx. Bractæas silky.—Native of New South Wales, from whence specimens, drawings, and seeds, were early sent by Dr. White and others. It is rather difficult to raise and to preserve, but when in perfection proves a great ornament to the greenhouse from June to August. The stem is erect, but very slender, and rather weak, bushy, with numerous, opposite, spreading branches, all of reddish-brown, hairy and round. Leaves opposite, on short stalks, acute, entire, convex, rigid, smooth, about an inch long; glaucous beneath. *Stipulas* in pairs, lanceolate, membranous, brownish. *Flowers* numerous, inodorous, large, on shortish, simple, axillary, crowded stalks, with a pair of bractæas under

the *calyx*, which like them is silky. *Standard* and *wings* of an orange yellow, the former crimson at the back, as well as at the centre in front; wings pale, tipped with crimson. *Legume* an inch and a half long, and half as broad, obtuse, with a little sharp point, somewhat hairy all over.

2. *P. parviflorum*. Small-flowered Flat-pea. Sm. Bot. of N. Holl. 18. Willd. n. 2. Ait. n. 2. Curt. Mag. t. 1520.—Leaves lanceolate-ovate. Germen nearly smooth. Stalk of the legume longer than the calyx. Bractæ smooth.—From the same country. Sent to Kew by Sir J. Banks in 1792. It blooms in the summer, amongst other greenhouse shrubs.

3. *P. triangulare*. Triangular-leaved Flat-pea. Brown MSS. Ait. n. 3. Curt. Mag. t. 1508.—“Leaves somewhat triangular or hastate, with spinous angles. Flower-stalks bracteated at the base and summit, naked in the middle. Legume several times longer than the calyx.—Gathered by Mr. Brown in Van Diemen’s island, and sent to Kew in 1805. It is kept in the greenhouse, and flowers from June to September.

PLATYOPHTHALMON, a name given by some to antimony, from its use among the ladies of old time, to make their eye-brows broad and black.

PLATYPUS, *Duck-billed Platypus*, in *Zoology*, a genus of the class and order Mammalia Bruta, of which the generic character is; mouth shaped like the bill of a duck; the feet are palmate. There is but a single

Species.

ANATINUS. This extraordinary animal is placed by Dr. Shaw next to the genus *Myrmecophaga*. The description of this naturalist, who has taken much pains in investigating the characters of the genus, we shall transcribe, as being the only satisfactory account we have of it. “Of all the mammalia yet known, it seems the most extraordinary in its conformation, exhibiting the perfect resemblance of the beak of a duck engrafted on the head of a quadruped. So accurate is the similitude, that, at first view, it naturally excites the idea of some deceptive preparation by artificial means; the very epidermis, proportion, ferratures, manner of opening, and other particulars of the beak of a shoveler, or other broad-billed species of duck, presenting themselves to the view: nor is it without the most minute and rigid examination that we can persuade ourselves of its being the real beak or snout of a quadruped.

“The body is depressed, and has some resemblance to that of an otter in miniature: it is covered with a very thick, soft, and beaver-like fur, and is of a moderately dark brown above, and of a subferruginous white beneath. The head is flattish, and rather small than large; the mouth or snout, as before observed, so exactly resembles that of some broad-billed species of duck, that it might be mistaken for such: round the base is a flat circular membrane, somewhat deeper or wider below than above, viz. below near the fifth of an inch, and above about an eighth. The tail is flat, furry like the body, rather short and obtuse, with an almost bifid termination; it is broader at the base, and gradually tapers to the tip, and is about three inches in length; its colour is similar to that of the body. The length of the whole animal, from the tip of the beak to that of the tail, is thirteen inches; of the beak an inch and a half. The legs are very short, terminating in a broad web, which on the fore feet extends to a considerable distance beyond the claws; but on the hind feet reaches no farther than the roots of the claws. On the fore feet are five claws, straight, strong, and sharp-pointed; the two exterior ones somewhat shorter than the three middle ones. On the hind feet are

six claws, longer and more inclining to a curved form than those on the fore feet; the exterior toe and claw are considerably shorter than the four middle ones; the interior, or sixth, is seated much higher up than the rest, and resembles a strong, sharp spur. All the legs are hairy above; the fore feet are naked both above and below; but the hind feet are hairy above and naked below. The internal edges of the under mandible (which is narrower than the upper) are serrated or channelled with numerous striæ, as in a duck’s bill. The nostrils are small and round, and are situated about a quarter of an inch from the tip of the bill, and are about the eighth of an inch distant from each other. There is no appearance of teeth; the palate is removed, but seems to have resembled that of a duck; the tongue also is wanting in the specimen. The ears or auditory foramina are placed about an inch beyond the eyes; they appear like a pair of oval holes of the eighth of an inch in diameter, there being no external ear. On the upper part of the head, on each side, a little beyond the beak, are situated two smallish oval white spots, in the lower part of each of which are imbedded the eyes, or at least the parts allotted to the animal for some kind of vision; for from the thickness of the fur, and the smallness of the organs, they seem to have been but obscurely calculated for distinct vision, and are probably like those of moles, and some other animals of that tribe; or perhaps even subcutaneous; the whole apparent diameter of the cavity in which they were placed not exceeding the tenth of an inch. When we consider the general form of this animal, and particularly its bill and webbed feet, we shall readily perceive that it must be a resident in watery situations; that it has the habits of digging or burrowing in the banks of rivers, or under ground; and that its food consists of aquatics, plants, and animals. This is all that can at present be reasonably guessed at: future observations, made in its native regions, will, it is hoped, afford us more ample information, and will make us fully acquainted with the natural history of an animal which differs so widely from all other quadrupeds, and which verifies, in a most striking manner, the observations of Buffon, viz. that whatever was possible for nature to produce, has actually been produced.”

Dr. Shaw observes, in a subsequent volume, as the result of more accurate experiments, that “on laying open the parts beyond the base of the bill, it appears that the platypus, like the ant-eaters, is furnished with small bony processes resembling grinding-teeth, imbedded in the gum, but not fastened or rooted in the jaw: of these processes, there are two on each side both of the upper and under jaw.” Shaw’s Gen. Zool. vol. i. and ii.

PLATYRYNCHOS, in *Ichthyology*, a name given by some to the nase, or nase, a fresh-water fish, caught in the Danube, and most of the large rivers in Germany, and much resembling the chub. See *CYPRINUS Nafus*.

PLATYSMA MYOIDES, in *Anatomy*, the thin stratum of muscular fibres placed immediately under the skin in the neck. It is described in the article *DEGLUTITION*, under the name of *latissimus colli*.

PLATYSTERNOS, a word used by the old physicians to express a person with a very broad chest or sternum.

PLATYZOMA, in *Botany*, from *πλατύς*, broad, and *ζώνη*, a belt, a genus of *Filices* in Mr. Brown’s *Prod. Nov. Holl.* v. 1. 160, nearly allied to *Gleichenia*, from which the author says he was induced to separate it, rather on account of its undivided stalks, which in *Gleichenia* are forked, than for the slight difference in the fructification. The latter seems principally to consist in the revolute margins of the leaflets forming a sort of *involutum*.

The

The only species mentioned is

1. *P. microphyllum*.—Found in the tropical parts of New Holland. A smooth fern, with a creeping scaly root. Stalks undivided. Fronds pinnate; leaflets extremely numerous, distinct, orbicular, entire, minute, covered beneath with sulphur-coloured powder. Capsules few together in each dot. Seeds rather large. Some fronds, from the same root, are compressed, nearly thread-shaped, and undivided. See GLEICHENIA.

PLATZ, in *Geography*, a town of Bohemia, in the circle of Bechin; seven miles W. of Fiftritz.

PLAU, or PLAUEN, a town of the duchy of Mecklenburg, on a lake called the "Plauer See;" 15 miles E. of Parchim. N. lat. 53° 50'. E. long. 12° 23'.

PLAVA, a town of Servia; 20 miles S.W. of Jenibafar.

PLAUEN, a town of Saxony, in the county of Schwartzburg, on the Gera; 16 miles N.W. of Schwartzburg. N. lat. 50° 45'. E. long. 11° 2'.—Also, a town of Saxony, in the Vogtland, on the Elster, in which is a manufacture of cotton and cloth; 22 miles S.W. of Zwickau. N. lat. 50° 23'. E. long. 12° 8'.—Also, a town of Brandenburg, in the Middle Mark, seated on a lake formed by the Havel, which gives name to a canal that runs from thence to the Elbe. This town has a manufacture of porcelain; six miles W. of Brandenburg. N. lat. 52° 29'. E. long. 12° 30'.

PLAUER SEE, a lake of the duchy of Mecklenburg, about 20 miles in circumference; E. of Plau.

PLAUSCHNITZ, a town of Bohemia, in the circle of Boleslaw; three miles E.S.E. of Turnau.

PLAUSEN, a town of Prussia, in Ermeland; 14 miles E. of Heilsberg.

PLAUSUS, among the Romans. See ACCLAMATION.

PLAUTEN, in *Geography*, a town of Prussia, in Oberland; 16 miles S.E. of Marienwerder.

PLAUTUS, MARCUS ACCIUS, in *Biography*, a celebrated Latin writer of comedy, was a native of Sarfina, a small town in Umbria. He was thought not only to have been of mean parentage, but the son of a slave. Few facts have come down to us that at all illustrate his life. He came to Rome, and obtained not only fame but emolument from his dramatic compositions, which were represented about a century and a half before the Christian era. Plautus is said to have acquired considerable property, and to have been tempted, in order to increase it, to engage in trade, but that, like many other literary speculators, he succeeded ill, that he was reduced to so great poverty, as to hire himself as a labourer to grind in a mill. Yet even in this toilsome situation his mind remained undepressed, and he composed three comedies. He died in the year 184 B.C. Anciently a great number of comedies were current under the popular name of Plautus, but of these the greater number was merely retouched by him, and the best Roman critics admitted only about twenty-five of his genuine compositions. Twenty of these are still extant, but some of them are in a mutilated state. Of the character they bore among his countrymen we have the most decided testimony. The learned Varro said, if the Muses were to speak Latin, they would use no other style than that of Plautus. By Cicero the wit of Plautus is called elegant, refined, ingenious, and facetious. "To a modern reader," says an able critic, "the humour of Plautus will often appear strong and genuine, but coarse and indelicate, and intermixed with quibbles and witticisms. His plays are, however, lively, and generally entertaining, and the language is a rich treasury of the Latin tongue. Many of his pieces, like those of

the other dramatists, are professed translations from the Greek, and it is probable that all his plots are borrowed from the Grecian theatre." The best editions of Plautus are the Variorum by Gronovius.

PLAUZAT, in *Geography*, a town of France, in the department of the Puy de Dôme; 10 miles S. of Clermont Ferrand.

PLAY, LUSUS. See GAME, and GAMING.

PLAY, in the *Doctrine of Chances*, is used for the probability of the play's ending in a given number of games.

PLAY, in *Poetry*, &c. See DRAMA, TRAGEDY, COMEDY, &c.

PLAYFORD, JOHN, in *Biography*, a stationer and musician, seller of musical books and instruments, and clerk of the Temple church.

In 1655 he published the first edition of his "Introduction to the Skill of Music," a compendium compiled from Morley, Butler, and other more bulky and abstruse books, which had so rapid a sale, that, in 1683, ten editions of it had been circulated through the kingdom. The book, indeed, contained no late discoveries or new doctrines, either in the theory or practice of the art; yet the form, price, and style, were so suited to every kind of musical readers, that it seems to have been more generally purchased and read, than any elementary musical tract that ever appeared in this or in any other country.

John Playford was born in the year 1613, and seems, by what means is now not known, to have laid in a considerable stock of musical knowledge, previous to becoming the vender of the chief productions of the principal composers of the time. As he was the first, so he seems the most intelligent printer of music during the seventeenth century; and he and his son Henry appear to have acquired the esteem of the first masters of the art; and without a special licence, or authorized monopoly, to have had almost the whole business of furnishing the entire nation with musical instruments, music books, and music paper, to themselves; as, during more than the first fifty years of the last century, Walsh and his son had afterwards.

In 1655, this diligent editor also published, in two separate books, small 8vo. "Court Ayres, by Dr. Charles Colman, William Lawes, John Jenkins, Simpson, Child, Cook, Rogers, &c."

These being published at a time when there was properly no court, were probably tunes which had been used in the masques performed at Whitehall during the life of the late king.

It was honest John Playford who new strung the harp of David, and published, in 1671, the first edition of his "Psalms and Hymns in solemn Musick, in four Parts on the common Tunes to Psalms in Metre used in Parish-churches. Also six Hymns for one Voice to the Organ," folio. The several editions of this work published in various forms, at a small price, rendered its sale very general, and psalm-singing in parts, a favourite amusement in almost every village in the kingdom.

PLAYFORD, HENRY, the second son of John, succeeded his father as a music seller, at first at his shop in the Temple, but afterwards in the Temple Exchange, Fleet-street.

The music books advertised by him were but few compared with those published by his father. Among them were the Orpheus Britannicus, and the ten sonatas and airs of Purcell.

Henry Playford published, in 1701, what he called the second book of the "Pleasant Musical Companion, being a choice collection of catches for three or four voices; published chiefly for the encouragement of the musical societies which

which will be speedily fet up in the chief cities and towns of England."

We know not what effect this advertizing title-page had upon the nation, but believe that the publication of Purcell's catches in two small volumes of the elder Walsh in queen Anne's time, was the means of establishing catch clubs in almost every town in the kingdom, where tobacco, ale, and psalm-singing were to be found.

It is conjectured that Henry Playford survived his father but a short time, for we meet with no publication by him after 1710.

PLAY-HOUSE. See THEATRE, AMPHITHEATRE, &c.

The most ancient English play-houses were the Curtain in Shoreditch, and the Theatre. In the time of Shakspeare, who commenced a dramatic writer about the year 1592, there were no less than ten theatres open, four private houses, and six that were called public theatres. Most, if not all of Shakspeare's plays, were performed either at the Globe, which was an hexagonal building, partly open to the weather, and partly covered with reeds, on the southern side of the river Thames, called the Bank-side, and a public theatre, where they always acted by day-light; or at the theatre in Black-friars, which was a private play-house, and where plays were usually represented by candle-light. Both these belonged to the same company of comedians, viz. his majesty's servants, which title they assumed after a licence had been granted to them by king James, in 1603; having before this time been called the servants of the lord chamberlain. The exhibitions at the Globe seem to have been calculated chiefly for the lower class of people, and those at Black-friars for a more select and judicious audience. The former was a summer, and the latter a winter theatre. Many of our ancient dramatic pieces were performed in the yards of carriers' inns, in which, in the beginning of queen Elizabeth's reign, the comedians, who then first united themselves in companies, erected an occasional stage. The form of these temporary play-houses seems to be preserved in our modern theatres. Many circumstances concur to render it probable, that our ancient theatres, in general, were only furnished with curtains, which opened in the middle, and a single scene composed of tapestry, sometimes ornamented with pictures. In the year 1605, Inigo Jones exhibited an entertainment at Oxford, in which moveable scenes were used; but they were not then used in the public theatres. When sir William Davenant first opened, by virtue of his patent, the duke of York's theatre in Lincoln's-inn-fields, in the spring of the year 1662, with one of his own plays, the Siege of Rhodes, then scenes made their first appearance upon the English stage; and about the same time actresses were also introduced, probably by him, in imitation of the foreign theatres; and Mrs. Betterton is said to have been the first woman that appeared on the English stage. Before this time, female characters were represented by boys or young men. In the time of Shakspeare plays began at one o'clock in the afternoon, and the exhibition was usually finished in two hours; and so late as 1667, they commenced at three o'clock. See Malone's Supplemental Observations to Stevens's edition of Shakspeare.

If any persons shall in plays, &c. jestingly or prophanely use the name of God, they shall forfeit 10*l*. (Stat. 1 Jac. I. cap. 21.) And players speaking any thing in derogation of religion, &c. are liable to forfeitures and imprisonment. (1 Eliz.) Also acting plays or interludes on a Sunday is subject to penalties, by 1 Car. I. cap. 1. No person shall act any new play, or an addition to an old one, &c. unless a true copy thereof, signed by the master of the play-house,

be sent to the lord chamberlain fourteen days before it be acted, who may prohibit the representing any stage play; and persons acting contrary to such prohibitions shall forfeit 50*l*. and their licences, &c. (Stat. 10 Geo. II. cap. 28.) And by this statute, no licence is to be given to act plays, but in the city and liberties of Westminster, or places of his majesty's residence. Ibid.

PLAZIA, in *Botany*, a genus in the Flora Peruviana, p. 92, named after John Plaza, a Spanish botanist, mentioned respectfully by Clusius. *De Theis*. 371.

PLEA, PLACITUM, in *Law*, that which either party allegeth for himself in court, in a cause then depending to be tried.

Pleas are either of *the crown*, or *common pleas*.

PLEAS of *the Crown* comprehend all crimes and misdemeanors, in which the king, on behalf of the public, is the plaintiff. Such are treasons, felonies, misprisions of either, and mayhem.

PLEAS, *Common*, include all civil actions depending between subject and subject. The former of these were the proper object of the jurisdiction of the court of king's bench; the latter of the court of common pleas.

PLEAS are of two sorts; viz. *dilatory* pleas, and pleas to the *action*. For an account of dilatory pleas, see DILATORY.

Pleas to the *action*, are such as dispute the very cause of suit.

A plea to the action is to answer to the merits of the complaint; which is done either by confessing or denying it. (See CONFESSION of *action*.) To this head may be referred the practice of what is called a "set-off;" by which the defendant acknowledges the justice of the plaintiff's demand on the one hand; but on the other, sets up a demand of his own to counterbalance that of the plaintiff, either in the whole or in part; as if the plaintiff sues for ten pounds due on a note of hand, the defendant may set off nine pounds due to himself for merchandize sold to the plaintiff, and in case he *pleads* such set-off, must pay the remaining balance into court. This answers very nearly to the *compensatio*, or *stoppage*, of the civil law (Ff. 16. 2. 1.), and depends on the statutes 2 Geo. II. c. 22. and 8 Geo. II. c. 24. which enact, that where there are mutual debts between the plaintiff and defendant, one debt may be set against the other, and either pleaded in bar, or given in evidence upon the general issue at the trial; which shall operate as payment, and extinguish so much of the plaintiff's demand.

Pleas that totally deny the cause of complaint are either the *general*, or a *special* plea, in bar. The *general* issue, or general plea, traverses, thwarts, and denies at once the whole declaration, without offering any special matter whereby to evade it. Thus, in debt on contract, it is, *nihil debet*, he owes nothing; in debt on bond, *non est factum*, it is not his deed; in action of the case upon a promise, *non assumpsit*, he hath not promised; in trespass upon the case, *not guilty*; in covenant, *performance of covenants*, &c. In real actions, *nul fort*, no wrong done; *nul disseisin*, no disseisin; and in a writ of right, that the tenant has more right to hold than the demandant has to demand. These pleas are called the general issue, because they amount at once to an issue, or a fact affirmed on one side, and denied on the other. Formerly the general issue was seldom pleaded, except when the party meant wholly to deny the charge alleged against him. But when he meant to distinguish, deny, or palliate the charge, it was always usual to set forth the particular facts in what is called a *special* plea; which was originally intended to apprise the court and the adverse party of the nature and circumstances of the defence, and to keep the law and

and the fact distinct. And it is an invariable rule, that every defence which cannot be thus specially pleaded, may be given in evidence, upon the general issue at the trial. Of late, on account of the chicane and delay that have attended special pleading, the courts have, in some instances, and the legislature in many more, permitted the general issue to be pleaded, thus leaving every thing open, the fact, the law, and the equity of the case, and have allowed special matter to be given in evidence at the trial.

Special pleas, in bar of the plaintiff's demand, are very various, according to the circumstances of the defendant's case. As, in real actions a general release, or a fine, both of which may destroy and bar the plaintiff's title. Or, in personal actions, an accord, arbitration, conditions performed, nonage of the defendant, or some other fact which precludes the plaintiff from his action. A *justification* is likewise a special plea in bar; as in actions of assault and battery, *son assault demesne*, that it was the plaintiff's own original assault; in trespass, that the defendant did the thing complained of in right of some office which warranted him so to do; or, in an action of slander, that the plaintiff is really as bad a man as the defendant said he was. A man may also plead the statutes of limitation in bar. (See *Statutes of LIMITATION*.) An estoppel is likewise a special plea in bar. See ESTOPPEL, BAR, and ABATEMENT.

The conditions and qualities of a plea are, 1. That it be single, and containing only one matter; for duplicity begets confusion. But by statute 4 & 5 Ann. c. 16. a man, with leave of the court, may plead two or more distinct matters or single pleas; as in an action of assault and battery, these three, not guilty, *son assault demesne*, and the statute of limitation. 2. That it be strict and positive, and not argumentative. 3. That it have convenient certainty of time, place, and persons. 4. That it answer the plaintiff's allegations in every material point. 5. That it be so pleaded as to be capable of trial. Special pleas are usually in the affirmative, sometimes in the negative, but they always advance some new fact not mentioned in the declaration; and then they must be averred to be true in the common form; "and this he is ready to verify." This is not necessary in pleas of the general issue; those always containing a denial of the facts before advanced by the other party, and therefore putting him upon the proof of them.

It is a rule in pleading that no man be allowed to plead specially such a plea as amounts only to the general issue, or a total denial of the charge; but in such case he shall be driven to plead the general issue in terms, whereby the whole question is referred to a jury. But if the defendant, in an assise or action of trespass, be desirous to refer the validity of his title to the court rather than to the jury, he may state his title specially, and at the same time *give colour* to the plaintiff, or suppose him to have an appearance or colour of title, bad indeed in point of law, but of which the jury are not competent judges. When the plea of the defendant is thus put in, if it does not amount to an issue, or total contradiction of the declaration, but only evades it, the plaintiff may plead again, and *reply* to the defendant's plea; either traversing it, that is, totally denying it; as if on an action of debt upon bond, the defendant pleads *solvit ad diem*, that he paid the money when due, here the plaintiff in his *replication* may totally traverse this plea, by denying that the defendant paid it; or he may allege new matter in contradiction to the defendant's plea; as when the defendant pleads *no award made*, the plaintiff may reply, and set forth an actual award, and assign a breach; or the replication may *confess and avoid* the plea, by some new matter or distinction, consistent with the plaintiff's former declaration; as, in an

action for trespassing upon land of which the plaintiff is seized, if the defendant shews a title to the land by descent, and that therefore he had a right to enter, and gives colour to the plaintiff, the plaintiff may either traverse and totally deny the fact of the descent; or he may confess and avoid it by replying, that true it is such descent happened, but that since the descent the defendant himself demised the lands to the plaintiff for term of life. To the replication the defendant may *rejoin*, or put in an answer called a *rejoinder*. The plaintiff may answer the rejoinder by a *sur-rejoinder*; upon which the defendant may *rebut*; and the plaintiff answer him by a *sur-rebutter*; which pleas, replications, rejoinders, sur-rejoinders, rebutters, and sur-rebutters, answer to the *exceptio, replicatio, duplicatio, triplicatio*, and *quadruplicatio* of the Roman laws. Inst. 4. 14. Braçt. l. 5. tr. 5. c. 1.

The whole of this process is denominated the *pleading*; in the several stages of which it must be carefully observed, not to depart or vary from the title or defence, on which the party has once insisted. For this (which is called a *departure* in pleading) might occasion endless altercation, therefore the replication must support the declaration, and the rejoinder must support the plea, without departing out of it. As in the case of pleading no award made, in consequence of a bond of arbitration, to which the plaintiff replies, setting forth an actual award; now the defendant cannot rejoin that he hath performed this award, for such rejoinder would be an entire departure from his original plea, which alleged that no such award was made; therefore he has now no other choice, but to traverse the fact of the replication, or else to demur upon the law of it. Yet in many actions the plaintiff who has alleged in his declaration a general wrong, may, in his replication, after an evasive plea by the defendant, reduce that general wrong to a more particular certainty, by assigning the injury afresh with all its specific circumstances in such manner as clearly to ascertain and identify it, consistently with his general complaint; which is called a *new or novel assignment*. Although duplicity in pleading must be avoided for various reasons, yet it is often expedient to plead in such a manner, as to avoid any implied admission of a fact, which cannot with propriety or safety be positively affirmed or denied. And this may be done by what is called a *protestation*; by which the party interposes an oblique allegation or denial of some fact, protesting (by the gerund, *protestando*) that such a matter does or does not exist; and at the same time avoiding a direct affirmation or denial. The use of this protestation is to save the party from being concluded with respect to some fact or circumstance, which cannot be directly affirmed or denied without falling into duplicity of pleading; and which yet, if he did not thus enter his protest, he might be deemed to have tacitly waived or admitted.

In any stages of the pleadings, when either side advances or affirms any new matter, he usually avers it to be true, "and this he is ready to verify;" on the other hand, when either side traverses or denies the facts pleaded by his antagonist, he usually tenders an issue, as it is called; the language of which varies with the party by whom the issue is tendered; for if the traverse or denial comes from the defendant, the issue is tendered thus, "and of this he puts himself upon the country," thereby submitting himself to the judgment of his peers; but if the traverse lies upon the plaintiff, he tenders the issue, or prays the judgment of the peers against the defendant in another form; thus, "and this he prays may be inquired of by the country." But if either side (*e. g.* the defendant) pleads a special negative plea, not traversing or denying any thing that was before alleged,

alleged, but disclosing some new negative matter; as when the suit is on a bond, conditioned to perform an award, and the defendant pleads negatively, that no award was made, he tenders no issue upon this plea; because it does not yet appear whether the fact will be disputed, the plaintiff not yet having asserted the existence of any award; but when the plaintiff replies, and sets forth an actual specific award, if then the defendant traverses the replication, and denies the making of any such award, he then, and not before, tenders an issue to the plaintiff. For when, in the course of pleading, they come to a point which is affirmed on one side, and denied on the other, they are then said to be at issue; all their debates being at last contracted into a single point, which must now be determined either in favour of the plaintiff or defendant. Blackst. Com. b. iii.

PLEA, in *Equity*, may be either to the jurisdiction, shewing that the court has no cognizance of the cause; or to the person, shewing some disability in the plaintiff, as by outlawry, excommunication, and the like; or in bar, shewing some matter, wherefore the plaintiff can demand no relief, as an act of parliament, a fine, a release, or a former decree. And the truth of this plea the defendant is bound to prove, if put upon it by the plaintiff.

PLEA to *Indictment*, is the plea of the prisoner, or defensive matter alleged by him on his arraignment, if he does not confess, or stand mute. Waiving the plea of sanctuary, which is now abrogated (see SANCTUARY); there are five pleas of this kind. 1. A plea to the jurisdiction, which is when an indictment is taken before a court that hath no cognizance of the offence; as if a man be indicted for a rape at the sheriff's tourn, or for treason at the quarter-sessions; in these, or similar cases, he may except to the jurisdiction of the court, without answering at all to the crime alleged. (2 Hal. P. C. 256.) 2. A demurrer to the indictment. (See DEMURRER.) 3. A plea in abatement, which is principally for a misnomer, a wrong name, or a false addition to the prisoner. But the prisoner derives little benefit from dilatory pleas of this kind; because, if the exception be allowed, a new bill of indictment may be framed, according to what the prisoner in his plea avers to be his true name and addition. 4. A special plea in bar, which affects the merits of the indictment, and gives a reason why the prisoner ought not to answer it at all, nor put himself upon his trial for the crime alleged. These pleas are of four kinds: a former acquittal, a former conviction, a former attainder, or a pardon. Here we may observe that, though in civil actions, in which a man may chuse what plea in bar to make, he is concluded by that plea and cannot recur to another; in criminal prosecutions, when a prisoner's plea in bar is found against him upon issue tried by a jury, or adjudged against him in point of law by the court, still he shall not be concluded or convicted thereon, but shall have judgment of *respondent ouster*, and may plead over to the felony the general issue, not guilty. (2 Hal. P. C. 239.) For the law allows many pleas by which the prisoner may escape death; but only one plea, in consequence of which it can be inflicted, *viz.* on the general issue, after an impartial examination and decision of the facts, by the unanimous verdict of a jury. 5. The general issue, a plea of *not guilty*, upon which plea alone the prisoner receives his final judgment of death.

PLEA in *Bar of Execution*, may be either insanity, pregnancy, the king's pardon, an act of grace, or diversity of person, *viz.* that he is not the same that was attainted and the like. In this last case a jury shall be impanelled to try this collateral issue, *viz.* the identity of his person,

and not whether guilty or innocent; for that has been decided before. In these collateral issues, the trial shall be *instant*, and no time allowed the prisoner to make his defence, or produce his witnesses, unless he will make oath that he is not the person attainted; neither shall any peremptory challenges of the jury be allowed the prisoner, though formerly such challenges were held to be allowable, whenever a man's life was in question.

PLEAS of the *Sword*. Ranulph earl of Chester, 2 Hen. III. granted to his barons of Cheshire an ample charter of liberties, "exceptis placitis ad gladium meum pertinentibus."

The reason of the exception was, that William the Conqueror gave the earldom of Chester to his half-brother Hugh, commonly called Lupus, ancestor of this Ranulph. "Tenere ita libere ad gladium, sicut ipse rex tenuit Angliam & coronam."

Accordingly, in all indictments for felony, murder, &c. in the county palatine, the form was, "Contra pacem domini comitis, gladium & dignitatem suam;" or, "Contra dignitatem gladii Cestrie." Such were the pleas for the dignity of the earl of Chester.

PLEAS, *Court of Common*, called also common bench. See COURT of *Common Pleas*.

PLEADING, PLACITATIO, a discourse spoken at the bar, in defence of the cause of a party.

From the time of the Conquest, all pleading was performed in French till the time of Edward III. when it was appointed, that the pleas should be pleaded in English, but that they should be entered, or recorded, in Latin. But now by 4 Geo. II. cap. 26. it is enacted, that all proceedings in courts of justice shall be in English.

At Athens, and even in France and England, it was prohibited to have any formed, or prepared pleading, or to amuse the court with long artificial harangues; only, in important matters, it was the settled custom to begin the pleadings with a passage in holy scripture.

It is but of late years that eloquence was admitted to the bar, where it has been much practised and encouraged.

Among the Athenians, an equal time was allowed both parties to plead, which was measured by a water hour-glass; and in order to see justice done in this respect, there was an officer appointed to distribute the water to each; whence he was called *ephydor*.

PLEADINGS, in the strictest sense, are all the allegations of the parties to a suit, made after the count, or declaration, till issue is joined: or, more generally, *pleadings* are the mutual altercations between the plaintiff and defendant; which at present are set down and delivered into the proper office in writing, though formerly they were usually put in by their counsel *ore tenus*, or *viva voce*, in court, and then minuted down by the chief clerks, or prothonotaries; whence in our old law French, the pleadings are frequently denominated the *parol*. The first of these is the *declaration*, which see. When the plaintiff hath stated his case in the declaration, it is incumbent on the defendant within a reasonable time to make his *defence*, and put in a *plea*; or else the plaintiff will at once recover judgment by *default*, or *nihil dicit* of the defendant. (See DEFENCE.) After defence made, the defendant must put in his *plea*. But, before he defends, if the suit is commenced by *capias* or *latitat*, without any special *original*, he is entitled to demand one *imparlance*, or *licentia loquendi*; and may, before he pleads, have more granted by consent of the court; to see if he can end the matter amicably without farther suit, by talking with the plaintiff; a practice which is supposed to have arisen from a principle of religion, in obedience to the precept of the gospel (Matth. v. 25.); which

which precept has a plain reference to the Roman law of the 12 tables, which expressly directed the plaintiff and defendant to make up the matter, while they were *in the way*, or going to the prætor. There are many other previous steps which may be taken by a defendant before he puts in his plea. When these proceedings are over, the defendant must then put in his excuse or plea. For an account of the different pleas, and the further process by pleading; see PLEA, *supra*.

PLEASANT, in *Geography*, a town of Clermont county, in Ohio, containing 1245 inhabitants.—Also, in Fairfield county, containing 988 inhabitants.

PLEASANT, *Mount*. See MOUNT Pleasant; adding in that article after Pennsylvania, containing, in 1810, 1105 inhabitants.—Also, *Mount Pleasant* in Washington county, containing 1165; and *Mount Pleasant* in Westmoreland, containing 1780 inhabitants, both in the same state.—Also, in Jefferson county, Ohio, containing 846 inhabitants.

PLEASANT *Point*, a N.E. headland in Merry-meeting bay, Lincoln county and state of Maine.—Also, a fertile and agreeably situated point of land, on the western bank of the Passamaquoddy river, about 15 miles from the mouth of the river, and four above Moose island. On this point reside the remains of the Passamaquoddy tribe of Indians, consisting of about 400 in number, and thought to be on the decline. They have a Roman Catholic priest, and lately, a respectable meeting-house has been erected at the expence of the state. Unacquainted with agriculture, their summer employment is that of fishing, and shooting porpoises, the oil of which they extract, and sell to the Americans for the use of lamps; and in winter they occupy themselves in hunting. They have some idea of moral obligation, but are not distinguished for their honesty or fidelity. The women are graceful and delicate in their manners, and modest in their dress. The men are fullen and unfociable.—Also, the eastern boundary of Hawk's, or Sandwich river, in the harbour of Chebucto.

PLEASANT *River*, a small village, with a post-office, on the sea-coast of Washington county, in Maine, at the head of Narraguagus bay; 16 miles N.E. of Goldborough.

PLEASURE, the effect of a sensation, or perception, agreeable to the mind, or of the gratification of some appetite.

Pleasures may be distinguished into two kinds. The first, those which anticipate, or go before the reason: such are all agreeable sensations. These are popularly called *pleasures of sense*, or *of the body*.

The second are those which do not precede, or anticipate, either the senses or reason. These we call *pleasures of the mind*. Such is the joy arising from a clear perception of some future good, or the confused sensation of a present one.

For an instance of each. A man frequently finds pleasure in eating a fruit he was before unacquainted with; this is *anticipating pleasure*, which he feels before he knows the fruit to be good. On the other hand, a hungry hunter expects, or perhaps actually finds victuals; where the joy he conceives is a pleasure that follows from the knowledge of his present or future good.

Pleasure and *pain* seem to be no other than engines in nature's hand, by which we are directed to consult our own preservation, and avoid our ruin. To things that may contribute to the one, as food, &c. she has annexed pleasure; and to those that may conduce to the other, as hunger, diseases, &c. pain.

Among the multiplicity of things to be done, and to be avoided, for the preservation of animal life, &c. how should

we have distinguished between the one and the other, but for the sensation of pleasure or pain? These are not only spurs to urge us on, but also guides, to direct us whither we are to go. Wherever nature has fixed a pleasure, we may take it for granted, she there enjoins a duty; and something is to be there done, either for the individual, or for the species.

Hence it is, that our pleasures vary at different stages of life; the pleasures, *e. gr.* of a child, a youth, a grown man, an old man, - &c. all tending to those particular things required by nature in that particular state of life, either for the preservation, simply, or, jointly, for that and propagation, &c.

Hence, from the different constitutions of the body, at different ages, it were very easy to account for all the particular tastes and pleasures thereof: not by deducing the pleasures mechanically from the disposition of the organs in that state, but by considering what is necessary for the perfection and well-being of the individual in that state, and what is to contribute to that of the species. In a child, *e. gr.* mere preservation in the present state is not enough, it must likewise grow: to bring this to pass, nature has made the returns of hunger, &c. more frequent, as well as more acute, and the pleasures of feeding more exquisite. And that the excess of aliment, in proportion to the bulk of the body, may be dispensed with, she has made one of the great pleasures of the state to consist in a series of sportive exercises; by means of which the parts of the body come to be opened and expanded, and arrive at maturity. This done, the pleasures that conduced to it disappear; and others, suited to the new state, succeed.

In the Hartleyan system, the capacity of pleasure and pain is one of the faculties of the human mind, by which a man becomes capable of action, enjoyment, or suffering. Our affections, or passions, are feelings arising from the perception of pleasure or pain, or, in other words, of natural good or evil, according to the circumstances in which they are placed. "By the affections," says Dr. Hartley, "we are excited to pursue happiness and all its means, and to flee from misery and all its apparent causes." The primary affections in his system are ten; five grateful, and five ungrateful: the former are love, desire, hope, joy, and pleasing recollection: the latter are hatred, aversion, fear, sorrow, and displeasing recollection. (See AFFECTION and PASSION.) The existence of this capacity of pleasure and pain we derive from consciousness; and what pleasure and pain are, we learn from experience; these being feelings which cannot be expressed by definition. Natural good produces pleasure, and that which produces pain is natural evil. Our pleasures and pains are either sensible or intellectual, that is, they are the effect of either sensations or ideas. The pleasurable and painful sensations he thus explains by his theory of vibrations. Moderate vibrations are the causes of pleasure, whilst violent vibrations occasion pain; hence the same sensation, which in a moderate degree is pleasurable, may, by increasing beyond certain limits, become exquisitely painful, as in the case of heat. Dr. Hartley conjectures, that the precise limit between pleasure and pain is the solution of continuity in the nerve that vibrates. Hence, Hartley and his disciples also account for the pleasure which accompanies the recovery from painful disorders, and from the recollection of past pains, dangers, and troubles. The vigorous vibrations, which occasion pain, subside by length of time within the limits of pleasure. Hence, it has been suggested, we may account, at least in part, for the existence of evil in the universe, and are able to assign a reason, why a state of probation, to beings constituted like ourselves, should be in a considerable degree a state of suffering.

ing. Pains the most exquisite and durable, it has been said, may ultimately fall within the limits of pleasure, and may be even essential to the production of the greatest good. Dr. Hartley, in the sequel of his "Treatise on Man," has shewn how, upon his system of association and vibration, our five senses, *viz.* feeling, taste, smell, sight, and hearing, produce intellectual pleasures and pains, or the different affections, which are modifications of pleasure and pain. Arranging the affections under six general classes, *viz.* imagination, emulation, self-interest, sympathy, theopathy, and the moral sense; he traces them up to the association of ideas, and deduces them either from sensible pleasures or pains, which are evidently original, or from the combination of other intellectual pleasures or pains, which are derived from sensible ones. The pleasures and pains of imagination arise from the perception of natural or artificial beauty or deformity; and these he distinguishes into seven kinds. The pleasures and pains of ambition arise from the opinions of others concerning us; the sense of honour and of shame. Those of self-interest arise from the possession or want of the means of happiness, and security from a subjection to the hazards of misery. (See SELF-INTEREST.) For the pleasures and pains of sympathy, theopathy, and the moral sense, see these several articles. See also *Mental PHILOSOPHY*.

PLEASURE Boat, among the *Ancients*. See *THALAMEGUS*.

PLEASURE Garden, in *Ornamental Gardening*, is that sort of garden which is formed near to, or that surrounds a country-house or residence; and which is contrived for the purpose of curiosity, ornament, or entertainment. This sometimes comprehends the whole pleasure ground, but at other times is totally distinct from it. Pleasure gardens should constantly be laid out according to the nature and situation of the particular places where they are to be formed, being of greater or less extent as circumstances may direct. They are mostly planted either wholly or in the greatest part with flowers and shrubs of the more beautiful and ornamental kinds, that they may afford as much beauty and variety as possible. In their forms they may be square, oblong, or somewhat circular, and have the boundaries of the divisions formed by the arrangements of curious shrubberies, embellished with collections of the most rare, beautiful, and curious flowering shrubs; the interior parts being divided into many narrow compartments, either in the parterre method with straight beds and borders, or into plain four-foot wide beds arranging parallel, with two-foot wide alleys between each, walks being carried all round next to the outer boundaries, after which borders surrounding the whole divisions, and within these the different divided parts for the beds, as already noticed, which should in general be raised in a gently rounding manner, the edges being set with dwarf-box, thrift, and pinks by way of variety, and the alleys and walks laid with the best and finest gravel.

In these divisions may be planted the most curious and valuable hyacinths, tulips, polyanthos-narcissuses, jonquils, ranunculuses, anemones, as well as most other sorts of rare, hardy, bulbous, and tuberous-rooted flowers, each kind mostly in a separate manner, especially of those of the more choice sorts, as being necessary, not only for the sake of distinction, but for the convenience of occasionally giving them protection from severe and inclement weather. In these situations, there may likewise be put out curious collections of the finest descriptions of fibrous-rooted flowering plants, such as carnations, polyanthuses, auriculas, and many other kinds, some of which being placed in separate beds, as those of the more valuable sorts, and others dispersed in different compartments, in order to give the

greatest possible degrees of variety. Still further, in other compartments, there may be exhibitions containing great varieties of all the different kinds of both the bulbous and fibrous-rooted sorts of flowering plants.

Gardens of this kind should constantly, in every part, be kept clean, neat, and perfectly in order.

PLEASURE Ground, in *Gardening*, any sort of ornamented ground round a residence. It comprehends all the ornamental compartments or divisions of ground and plantation; such as lawns, plantations of trees and shrubs, flower compartments, walks, pieces of water, &c. whether situated wholly within the space generally considered as pleasure ground, or extended over ha-has, or by other communications, to the adjacent fields, parks, paddocks, or out grounds.

In designs for pleasure grounds, modern improvements reject all formal works, such as long straight walks, regular interfections, square grass plots, corresponding parterres, quadrangular and angular spaces, inclosed with high clipped hedges, &c., as well as all other uniformities; instead of which, open spaces of grass ground of varied forms and dimensions, and winding walks, all bounded with plantations of trees, shrubs, and flowers, in various clumps and other distributions, are exhibited in a variety of imitative rural forms, as curves, projections, openings, and closings, in imitation of a natural assemblage, having all the various plantations open to the walks and lawns. A spacious open lawn of grass ground being generally first exhibited immediately in the front of the mansion, or main habitation, sometimes widely extended in open space on both sides to admit of greater prospect, &c., and sometimes more contracted towards the habitation, widening gradually outward, and having each side embellished with plantations of shrubbery, groves, thickets, &c., in clumps, and other parts, in sweeps, curves, and projections, towards the lawn, &c., with breaks or openings of grass spaces at intervals, between the plantations; and serpentine gravel walks winding under the shade of the trees; extended plantations being also carried round next the outer boundary of the ground, in various openings and closings, having also gravel walks winding through them, for shady and private walking; and in the interior divisions of the ground serpentine winding walks exhibited, and elegant grass openings, arranging various ways, all bordered with shrubberies, and other tree and shrub plantations, flower compartments, &c., disposed in a variety of different rural forms and dimensions, in easy bendings, concaves, projections, and straight ranges, occasionally; with intervening breaks or openings of grass ground between the compartments of plantations, &c., both to promote rural diversity, and for communication and prospect to the different divisions; all the plantations being so variously arranged, as gradually to discover new scenes, each furnishing fresh variety, both in the form of the design in different parts, as well as in the disposition of the various trees, shrubs, and flowers, and other ornaments and diversities.

So that in these designs, according to modern gardening, a tract of ground of any extent may have the prospect varied and diversified exceedingly, in a beautiful representation of art and nature, so that in passing from one compartment to another, new varieties present themselves in the most agreeable manner; and even if the figure of the ground be irregular, and its surface has many inequalities, in risings and fallings, and other irregularities, the whole may be improved without any great trouble of squaring and levelling, as by humouring the natural form, even the very irregularities may be made to conceal their natural deformities, and carry along with them an air of diversity and novelty.

In these rural works, however, we should not entirely abolish all appearance of art and uniformity; for these, when properly applied, give an additional beauty and peculiar grace to all natural productions, and set nature in the fairest and most advantageous point of view. One principal point in laying out a pleasure ground, is for the designer to take particular care that the whole extent of his ground be not taken in at one view, as where the contrary is the case, there is a tameness and want of proper effect produced.

It is impossible to give any directions for planting a pleasure ground; as the plan may be varied exceedingly, according to the natural figure, position, and situation of the land, and taste of the designer.

In respect to the situation, it must be immediately contiguous to the main house, whether high or low situated: however, a somewhat elevated situation, or the side or summit of some moderate rising ground, is always the most eligible on which to erect the chief habitation, arranging the pleasure ground accordingly; such an exposure being the most desirable, both for the beauty of the prospect and healthfulness of the air; a low level situation neither affording a due prospect of the ground, nor the adjacent country, besides being liable to unwholesome dampness, and sometimes inundation in winter: there are, however, many level situations, forming plains or flats, that possess great advantages both of soil and prospect, and the beauties of water without too much moisture; there are also sometimes large tracts of ground, consisting both of low and high situations, as level plains, hollows, eminences, declivities; and other inequalities, which may be so improved as to make a most desirable pleasure ground, as the scene may be varied in the most beautiful manner imaginable; but as the choice of situation and scope of ground is not always attainable, every one must regulate his plan in the most commodious manner possible, agreeable to the nature of the particular situation, extent of ground, and plan which has been adopted.

The extent of pleasure grounds may be varied, according to that of the estate or premises, and other circumstances, as from a quarter or half an acre to thirty or forty or more.

The ground for this purpose should previously be well fenced in, by a wall, paling, hedge, or parts of each sort, and in some parts a fosse or haia, where it may be necessary to extend the prospect, either at the termination of a lawn, walk, or avenue; and the close fences should generally be concealed withinside, particularly the wall and paling fences, by a range of close plantation, unless where the wall may be wanted for the culture of wall fruit. But sometimes, when the pleasure ground adjoins to a fine park, paddock, or other agreeable prospect, the boundary fence on that side is often either a low edge, or a haia; but many prefer the latter, especially at the termination of any spacious opening, both to extend the prospect more effectually, and give the ground an air of greater extent, than it really has, at a distance; the haia being sunk, nothing like a fence appears, so that the adjacent park, fields, &c. appear to be connected with the grounds.

The arrangement of the several divisions, both internal and external, must be wholly regulated by the nature and extent of the ground.

And in whatsoever mode such grounds are laid out, the whole of the different quarters, walks, and other parts, should be kept in an exact and neat order.

According to Mr. Loudon, the pleasure ground may consist of scenes of different expressions of avowed art, as those of gardening; and of nature, as those of picturesque

improvement, such as tranquil or sequestered glades, romantic glens, flowery meads, furzy heaths, tangled dingles, wooded dells, rocky steepes, and numberless others, which are to be met with in a varied or picturesque country, and are either to be heightened in effect, or preserved from cultivation by the improver. Wherever the pleasure ground is not under some of the particular scenes of ornamental gardening, it should be fed at least by sheep, and often by horses, cattle, &c., which should be allowed to come close to the terrace wall that separates the lawn from the mansion; for what can be more dull and unnatural, than the modern method of surrounding a house by a naked lawn totally destitute of animation?

A hollow winding dell or dingle, containing a brook or rill overhung with wood, and its banks diversified by broken ground presenting various coloured earths, and among the low growths old trunks of trees, roots, and stones, or dells of a grander character, containing bold, perpendicular, projecting, or irregular, massive rocks, overhung with huge trees, bushes, ferns, and creepers, grouped and combined in an infinite diversity of ways,—the stream, interrupted by the rocks, tumbling over in roaring cataracts, foaming cascades, or interrupted only by gentle falls,—and perhaps in some places, where the dell widens into a valley, spreading itself into a crystal lake, varied by little islands and woody projections, all heightened by the usual appendages of animation, the singing of birds, the fragrance of flowers, from what is considered to be among the most enchanting kinds of reclusive pleasure ground scenery. When a place is fortunate enough to have such a romantic chain of picturesque beauty as this, it should seldom be touched by the hand of art. It may happen, that some improvement may be made, by shewing, in a partial manner, rocks, roots, or stones, that are perhaps totally concealed; by augmenting a natural cascade, or by supplying ivy, or some other creepers, or evergreens, &c.; but in general little more can be attempted with propriety. The principal operation, that in any case can be undertaken in such a scene, is, where it may be requisite to lead through a walk, or road, either to observe its beauties, or as an approach to some other part of the residence. The difficulty of executing either of these will be great to those, who think of nothing but undulating sweeps, shaven lawns, and serpentine gravel walks; but by those accustomed to admire this kind of scenery, the operation will easily be accomplished. See RESIDENCE.

PLEASURE of the King, in *Law*, is used in connection with the infliction of punishment for any crime, not to signify any extrajudicial will of the sovereign, but such as is declared by his representatives, the judges in his courts of justice: “voluntas regis in curia, non in camera.” 1 Hal. P. C. 375.

PLEAU, LA, in *Geography*, a town of France, in the department of the Correze, and chief place of a canton, in the district of Tulle; 18 miles E. of Tulle. The place contains 655, and the canton 6355 inhabitants, on a territory of 232½ kilometers, in 8 communes.

PLEAUX, a town of France, in the department of the Cantal, and chief place of a canton, in the district of Mauriac; 8 miles S.W. of Mauriac. The place contains 2584, and the canton 10,667 inhabitants, on a territory of 182½ kilometres, in 12 communes.

PLEBANUS was anciently the title of a rural dean.

The denomination arose hence, that these deaneries were then affixed to the *plebania*, or chief mother-church within such a district; which, at first, was usually ten parishes.

PLEBANUS seems also to have been used for a parish-priest of such a large mother-church, as was exempt from the jurisdiction of the ordinary; so that he had the authority of

a rural dean committed to him by the archbishop; to whom the church was immediately subject.

PLEBEIAN, PLEBEIUS, a person of the rank of the populace, or common people.

The term is chiefly used in speaking of the ancient Romans; who were divided, about the time of Tarquin's expulsion, into senators, knights, and plebeians, or commons.

The plebeians were those who could not claim their descent from the ancient senators, appointed by Romulus, and the kings who succeeded him.

PLEBEIAN Games, were games celebrated by the Roman people, in remembrance, as some say, of their reconciliation with the senators, after the expulsion from the city, in the year of Rome 261; or, according to others, in token of their public rejoicing, when the kings were driven from Rome, A.U.C. 245, and the people enjoyed their liberty. These games were celebrated in the circus for three days, and commenced on the seventh of the calends of December. Adrian instituted plebeian games in the circus, A.U.C. 874.

PLEBISCITUM, among the Romans, a law enacted by the common people, at the request of the tribune, or some other plebeian magistrate, without the intervention of the senate.

PLEBISCITUM is more particularly applied to the law which the people made, when, upon some misunderstanding with the senate, they retired to the Aventine mount.

PLECH, in *Geography*, a town of Germany, in the principality of Culmbach; 21 miles S. of Pegnitz.

PLECHAS, a word used by Hippocrates to express that region of the body which is terminated backward by the anus, forward by the pudenda, and sideways by the hips.

PLECTANÆ, a word used by some to express the cornua uteri, and by others, for any plexus of vessels.

PLECTRANTHUS, in *Botany*, received that name from L'Heritier, in allusion to the *spur*, *πλεκτίς*, of the corolla, which he conceived to be an essential part of the generic character.—L'Herit. Stirp. 85. Schreb. 396. Willd. Sp. Pl. v. 3. 168. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 425. Brown Prodr. Nov. Holl. v. 1. 505. (Germanea; Juss. 116. Lamarck Illustr. t. 514.)—Class and order, *Didymia Gymnosperma*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, somewhat bell-shaped, short, two-lipped; upper lip ovate, broadest, ascending; lower four-cleft, acute, the two lower segments rather the longest. *Cor.* of one petal, ringent, reversed; tube compressed, longer than the calyx: one lip, which is turned uppermost, broadest, three-cleft; its middle segment very large, emarginate; lateral ones small: the other, directed downwards, narrower, entire, ovate, concave. Nectary a spur or prominence, from the base of the tube of the corolla, pointing upwards. *Stam.* Filaments four, declining, awl-shaped, two of them rather the shortest; anthers simple. *Pist.* Germen four-lobed; style thread-shaped, the length and position of the stamens; stigma cloven, acute. *Peric.* none, the calyx containing the four roundish seeds.

Ess. Ch. Upper lip of the calyx largest; lower four-cleft. Corolla reversed, ringent, its tube spurred on the upper side. Stamens simple.

Such are the characters of this genus, as originally defined by its author, who considered the reversed corolla, or flower; the spur or prominence of the tube; and the simple stamens; as essential marks. The two latter especially were supposed to distinguish it from *Ocimum*; see that ar-

tle. Mr. Brown however, looking more deeply into this latter genus, and finding several of its species without any tooth or appendage to their filaments, has referred such to *Plectranthus*, waving the consideration of the spur. He therefore gives the following character of *Plectranthus*.

Calyx two-lipped, striated, the lower lip divided; the base tumid beneath when in fruit. Upper lip of the corolla three-cleft, the middle segment two-lobed; lower lip longer, undivided, (mostly concave.) Stamens declining; their filaments without teeth, (sometimes united at the base;) anthers of one cell, beardless.

This includes, not only the *Plectranthus* of other authors, and the toothless species of *Ocimum*, but also the *Dentidia* and *Coleus* of Loureiro. Mr. Brown does not admit *Lavandula carnosifolia* into this genus, from which he says it differs in calyx and inflorescence, though agreeing in corolla, stamens and stigma, constituting, in his opinion, a genus by itself. (See *LAVANDULA*, at the end.) All the six New Holland species of Mr. Brown's *Plectranthus* are destitute of a spur. As the question is rather doubtful, while the whole genus of *Ocimum* requires to be critically examined, we shall here exhibit only such species of the genus before us as we conceive to answer to its original idea.

1. *P. fruticosus*. Shrubby *Plectranthus*. L'Herit. Stirp. 85. t. 41. Willd. n. 1. Ait. n. 1. (Germanea urticifolia; Lamarck Dict. v. 2. 690.)—Nectary spurred. Clusters compound. Flower-stalks three-cleft. Stem shrubby, downy.—Found at the Cape of Good Hope, from whence Mr. Maillon sent it in 1774 to Kew. This is a greenhouse shrub, flowering copiously from June to September. Every part has a fragrant scent. The stem is clothed with fine short down, unspotted. Leaves opposite, stalked, ovate, strongly serrated like those of a common nettle, veiny, roughish. Flowers copious, in pale violet clusters.

2. *P. galeatus*. Helmet *Plectranthus*. Vahl. Symb. v. 1. 43. Willd. n. 2.—Nectary gibbous. Partial flower-stalks branched. Leaves ovate, somewhat heart-shaped, pointed, serrated.—Native of Java. Stem villous, furrowed. Leaves stalked, broadly ovate, villous, especially the veins beneath. Cluster terminal; the flower-stalks opposite, branched, without bractees. Corolla downy; its lower lip hooded.

3. *P. nudiflorus*. Naked-flowered *Plectranthus*. Willd. n. 3.—Nectary gibbous. Panicle racemose, naked. Leaves heart-shaped, rugged; the upper ones clasping the stem.—Supposed to be a native of China; Willdenow having seen it in gardens under the name of *Ocimum chinense*. Root perennial. Stem erect, square, downy, scarcely six inches high. Lower leaves stalked, two or three inches long, coarsely toothed, rugose, smooth, except the veins at the back. Panicle a foot or more in length; each whorl of four clusters an inch long, turned one way, with two small heart-shaped bractees. Corolla small, closed, downy.

4. *P. Forskolii*. Bearded *Plectranthus*. Vahl. Symb. v. 1. 44. Willd. n. 4. Ait. n. 2. (*P. barbatus*; Andr. Repos. t. 594.)—Nectary gibbous. Clusters naked. Stem even, quadrangular.—Native of Arabia. *Forsk.* Commerçon gathered it in Madagascar and the Mauritius, and lord Valentia sent it to England in 1806. The whole herb is downy. Root tuberous, increasing prodigiously in its native soil. Leaves ovate, crenate, bluntish, stalked. Flowers in a long, whorled, upright cluster, pendulous, pale purple, hairy externally.

5. *P. crassifolius*. Thick-leaved *Plectranthus*. Vahl. Symb. v. 1. 44. Willd. n. 5.—Nectary gibbous. Clusters bracteated. Leaves ovate, fleshy.—Native of Egypt. Differs

Differs from the last, according to Vahl, in its fleshy leaves, and in having ovate membranous bractees.

6. *P. punctatus*. Dotted Plectranthus. L'Herit. Stirp. 87. t. 42; not 41. Willd. n. 6. Ait. n. 3. (*Ocymum punctatum*; Linn. Suppl. 275.)—Nectary gibbous. Clusters dense. Stem herbaceous, tumid, hairy.—Native of Africa, where it is said to have been found by Mr. Bruce the famous traveller. This species is biennial, flowering in the greenhouse from January to May. The tumid, fleshy, purple-dotted, hairy stem distinguishes it. The footstalks are short. Corolla very pale blue.

7. *P. carnosus*. Dense-spiked Plectranthus. (*Lavandula carnosa*; Linn. fil. Diff. 9. t. 2. Am. Acad. v. 10. 52. t. 3. Ait. Hort. Kew. v. 3. 383. Kato-Kurka; Rheede Hort. Malab. v. 10. 179. t. 90. *Nepeta indica*, rotundiore folio; Morif. Sect. 11. t. 6. f. 7.)—Nectary gibbous. Spikes ovate, dense. Leaves ovate, somewhat heart-shaped, fleshy, wavy or serrated.—Found by Koenig, on dry walls and rocks, at Sadras in the East Indies, flowering in the hottest season, after which the foliage appears. The stem is shrubby, but succulent, finely hoary. Leaves stalked, ovate or slightly heart-shaped, wavy, or more or less deeply serrated, very fleshy, minutely hoary, varying greatly in size. Spikes generally three or four to each branch, stalked, solitary and simple, ovate, thick, very much crowded, the calyces singularly reflexed, or imbricated downward. Corolla yellowish. Rheede speaks of this plant as aromatic, and useful against the bite of some serpents. It was sent to Kew in 1788 by sir Joseph Banks, and is kept in the stove, flowering in June and July; but the root is said to be only biennial.

PLECTRONIA, so named by Linnæus, from *πλεκτρον*, a cock's spur, which its thorns very much resemble.—Linn. Mant. 6. Schreb. 153. Willd. Sp. Pl. v. 1. 1152. Mart. Mill. Dict. v. 3. Juss. 382. Lamarck Illust. t. 146.—Class and order, *Pentandria Monogynia*. Nat. Ord. akin to *Rhamnifera*, Juss. Linnæus refers it to his *Convolvulæ*, in his Prælectiones in Ord. Nat. 408.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, with five slight teeth, the mouth closed with five hairy scales, permanent. Cor. Petals five, lanceolate, sessile, inserted into the mouth of the calyx. Stam. Filaments five, very short; anthers two-lobed, roundish, each sheltered by one of the scales of the calyx. Pist. Germen inferior; style thread-shaped, shorter than the calyx; stigma ovate. Peric. Berry oblong, of two cells. Seeds solitary, oblong, compressed.

Ess. Ch. Petals five, inserted into the mouth of the calyx, which is closed by five hairy scales. Berry inferior, with two seeds.

1. *P. ventosa*. Linn. Mant. 52. (*P. corymbosa*; Burm. Prodr. Cap. 6. *Rhamnus foliis subrotundo-acuminatis, fructu racemoso*; Burm. Afr. 257. t. 94.)—Native of woods at the Cape of Good Hope, flowering in September; a stranger, as yet, in our gardens. This is a tree, whose trunk and principal branches are armed with very considerable, long, tapering, simple, opposite spines. The leaves are opposite, stalked, elliptical, acute at each end, entire thick-edged, somewhat wavy and revolute, smooth on both sides; polished above; paler and opaque beneath; with one rib, and many transverse veins. Flowers small, yellow, in compound, axillary, dense clusters, about twice the length of each footstalk; their stalks opposite, angular, rather downy, with opposite, minute, deciduous bractees under their subdivisions.

We are at a loss for the meaning of the specific name given by Linnæus, which is not so good as Burmann's.

The tree is said to be well calculated for making hedges. The habit and appearance of every part seem rather to justify the opinion of Linnæus than of Jussieu, respecting the natural order to which this plant belongs, but the inferior germen, if it be really so, is adverse to both.

PLECTRONITÆ. See CONICHTHYODONTES.

PLECTRUM, a word used by some anatomical writers to express the styloid process of the os petrosum; by others for the uvula; and by others for the tongue.

PLECTRUM, *πλεκτρον*, a machine of wood or ivory used by the ancients in playing upon the lyre, crooked and pointed at both ends, in using which there was more spirit given to the tone, and less danger of hitting the wrong string than by using the finger. The quill used in playing on the mandoline, is in miniature what we may suppose the plectrum to have been with respect to the lyre.

PLEDGE, in Law. See VADTUM.

PLEDGE. See PROCESS.

PLEDGE, *Plegius*, a surety, or gage, either real or personal, which the plaintiff, or demandant, is to find, for his prosecuting the suit.

The word is sometimes also used for frank pledge.

To PLEDGE, in Drinking, denotes to warrant, or be surety to one, that he shall receive no harm while he is taking his draught.

The phrase is referred, by our antiquaries, to the practice of the Danes, heretofore, in England; who frequently used to stab, or cut the throats of the natives while they were drinking.

PLEDGERY, or PLEGGERY, suretyship, or an undertaking, or answering for another.

The appellant shall require the constable and marshal to deliver his pleggs, and to discharge them of their pledgery; and the constable and marshal shall ask leave of the king to acquit his pleggs, after that the appellant is come into the lists to do his devoir. Orig. Jur. ex Vet. Cod. MS. in Bibl. Selden.

PLEDGES of Goods for Money, &c. See PAWN and BAILMENT.

PLEDGET, in Surgery, a kind of flat tent, made not to enter a wound, but to be laid upon it, to imbibe the superfluous humours, and keep it clean and dry.

PLEEA, in Botany, a name of Michaux's, which seems intended to express the superabundance of itamens compared with others of its kindred, from *πλεον*, more. Mich. Boreal. Amer. v. 1. 247. Parth. Am. Sept. v. 1. 275.—Class and order, *Enneandria Trigynia*. Nat. Ord. *Tripetaloidæ*, Linn. Junci, Juss.

Gen. Ch. Cal. Sheath of one leaf. Cor. of one petal, divided to the base into six spreading, nearly equal, linear-lanceolate, acute segments, permanent. Stam. Filaments nine, awl-shaped, shorter than the corolla, inserted into the base of its segments; anthers oblong, versatile, of two cells, opening lengthwise. Pist. Germen superior, oblong, triangular; styles none; stigmas three, sessile, linear, obtuse. Peric. Capsule covered by the permanent closed corolla, roundish-triangular, of three cells, without any manifest partitions, except the inflexed margins of the valves, the cells bursting longitudinally at their inner edge, the valves splitting at the top. Seeds numerous, oblong, cylindrical, slightly curved, inserted into the margins of the valves, each by a short stalk.

Ess. Ch. Corolla in six deep spreading segments. Capsule triangular, of three cells. Seeds numerous, oblong, inserted into the margins of the valves. Sheaths simple, single-flowered.

1. *P. tenuifolia*. Michaux Boreal. Amer. v. 1. 248. t. 25. Pursh

Pursh v. 1. 278.—The only species; a native of open wet woods in Lower Carolina. *Michaux.* The root is perennial, resembling that of an *Iris*. Leaves few, radical, sheathing at the base, erect, very narrow, smooth, flattened, taper-pointed, about half as tall as the common flower-stalk, which is radical, about a foot and half high, simple, erect, round, smooth, nearly naked. Cluster terminal, erect, simple, of six or eight yellowish-brown stalked flowers, the size of *Ornithogalum umbellatum*, each accompanied by a tubular pointed sheath as long as the flower of its stalk. This plant agrees in number of stamens, though not of pistils, with our *Butomus umbellatus*, a genus of the same natural order, but the structure of the seeds, and their infertion, are both different, as well as the inflorescence.

PLEGII de Retorno, &c. in *Latv.* See REPLEVY and RETORNO *Habendo*.

PLEGIIS ACQUIETANDIS, a writ that lies for a surety, against him for whom he is surety, in case he pay not the money at the day. Fitz. Nat. Brev.

PLEGORRHIZA, in *Botany*, from *πληρον*, a wound, and *ρίζα*, a root, because the root of this plant is used by the inhabitants of Chili as a vulnerary. Molin. Chil., the German edition, 140. Willd. Sp. Pl. v. 2. 487. Juss. 438.—Class and order, *Enneandria Monogynia*.

Eff. Ch. Calyx none. Corolla of one petal. Capsule of one cell. Seed solitary.

1. P. *adstringens*. Willd. n. 1. (P. Guajcuru; Molina as above.)—Native of the northern provinces of Chili. Stem woody. Radical leaves collected into a tuft, stalked, oval, simple, undivided; those on the branches sessile, ovate. Flowers numerous, stalked, terminal. Corolla undivided. Stamens nine, very short. Anthers oblong. Germen orbicular. Style cylindrical, the length of the stamens. Stigma simple. Capsule oblong, rather compressed. Seed of the same shape. Jussieu reckons a calyx, what Willdenow, as above, terms corolla, and advises that the genus should be compared with his orders of *Lauri* and *Polygonæ*.

PLEGRA, in *Ancient Geography*, a town of Asia, in the interior of Galatia, in the country of the Paphlagonians: placed by Ptolemy between Zagira and Sacora.

PLEIADES, Πλειάδες, in *Astronomy*, an assemblage of seven stars in the neck of the constellation Taurus.

They are thus called from the Greek *πλεω*, *navigare*, to sail; as being terrible to mariners, on account of the rains and storms that frequently rise with them.

The Latins call them *vergilie*, from *ver*, *spring*; because of their rising about the vernal equinox.

The largest is of the third magnitude, and is called *Lucida Pleiadum*. See TAURUS.

There are now only six stars visible in Pleiades, and this appears to have been the case so long ago as the time of Ovid:

“Quæ septem dici, sex tamen esse solent.”

PLEIADES, in *Mythology*, were the seven daughters of Atlas, called Maya, Electra, Taygeta, Asteropa, Alcione, Celeno, and Merope. These Atlantides, it is said, were translated to the heavens, and formed the Pleiades; the meaning of which fable is, that Atlas first observed these stars, and called them by the names of his daughters.

PLEIADES, *Poetical*, is a name which the Greeks gave to seven celebrated poets, flourishing under the reign of Ptolemy Philadelphus.

In imitation of the Greeks, Ronfard formed a Pleiades of French poets under the reign of Henry II. It consisted of Daurat, Ronfard, du Bellay, Belleau, Baif, Tyard, and Jodelle.

On the same model, some of their authors afterwards projected a new Pleiades of the Latin poets of the last century; but they were not agreed about the names of those that should compose it; much less on him who should be the Lucida Pleiadum. M. Baillet named F. Rapin, F. Commire, F. de la Rue, M. de Santeuil, M. Menage, M. du Perier, and M. Petit.

PLEIN RIVER, in *Geography*, the northern head-water of Illinois river; it interlocks with Chicago river, a water of lake Michigan, and five miles below Dupage lake, through which it passes; it joins Theakiki river, which comes from the eastward. Thence the united stream takes the name of Illinois. The land between these branches is rich, and intermixed with swamps and ponds.

PLEINFELD, or BLEINFELD, a town of Bavaria, insulated in Anspach; 22 miles S.E. of Anspach. N. lat. 49° 3'. E. long. 10° 55'.

PLEINEFOUGE'RES, a town of France, in the department of the Ille and Villaine, and chief place of a canton, in the district of St. Malo. The town contains 2726, and the canton 12,878 inhabitants, on a territory of 167½ kilometres, in 11 communes.

PLEINTING, a town of Bavaria, on the Danube; 5 miles S.S.E. of Otterhof.

PLEISKE, a river of Brandenburg, which runs into the Oder; 9 miles above Francfort.

PLEISNITZ, a town of Hungary, 25 miles W. of Caschau.

PLEISSA, a river of Saxony, which runs into the Elster, near Leipzig.

PLEISSEN, or PLEISSA, a lordship of Germany, in the principality of Hesse Rhinfels, insulated in the duchy of Brunswick. It takes its name from an old castle situated on a mountain.

PLEISVEDEL, a town of Bohemia, in the circle of Leitmeritz; 8 miles S.W. of Leypa.

PLE'LAN, a town of France, in the department of the Ille and Villaine, and chief place of a canton, in the district of Montfort; six posts E.N.E. of Vannes. The place contains 2917, and the canton 13,316 inhabitants, on a territory of 325 kilometres, in 8 communes.—Also, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Dinan; 6 miles E. of Loudeac. The place contains 854, and the canton 3903 inhabitants, on a territory of 122½ kilometres, in 9 communes.

PLEMMYRIUM, in *Ancient Geography*, a promontory on the eastern coast of Sicily, over-against Syracuse, of which it was the port, according to Thucydides. It is also mentioned by Virgil.

PLEMMYRÓS, a word used by the old Greek writers to express a redundancy of humours. Its proper signification is the flowing in of the tide.

PLEMPIUS, VOPISCUS FORTUNATUS, in *Biography*, an eminent physician, was born at Amsterdam, of a distinguished family, in December 1601. He received his classical education at Gand, and studied philosophy at Louvain, whence he repaired to Leyden, and commenced his medical studies. He subsequently travelled into Italy, and passed the principal portion of his time at Padua and Bologna, having the advantage of pursuing his anatomical investigations under the direction of Spigelius at the former place, and of taking his degree of doctor at the latter. On his return to Holland, he settled in the practice of his profession in his native city, where he acquired a high reputation; and was induced to accept the invitation of Isabella, princess of the Low Countries, to the vacant professorship of

of the Institutes of Medicine, at Louvain, of which he took possession in 1633. At the same time he abjured the Protestant faith, became a Catholic, and took a new degree of doctor, in conformity with the rules of the university. In the following year, however, he quitted this chair, for the professorship of pathology. He was soon afterwards nominated principal of the college of Breugel. He died at Louvain in December 1671, aged seventy.

Plempius increased the reputation of Louvain by the extent of his attainments, and was an able controversialist, distinguishing himself in all the public questions that came under discussion. He left the following works. "A Treatise on the Muscles," in Dutch. "Ophthalmographia, five de Oculi Fabricâ, Actione, et Ufu," Amst. 1632; Lovæn. 1648. A translation of the Anatomy of Cabrolus into Dutch, with notes; Amst. 1633. "Fundamenta, seu Institutiones Medicinæ;" Lov. 1638, 1644, &c. In the first edition of this work, Plempius doubted the circulation of the blood; but in the second, he was a strenuous advocate for that doctrine. "Animadversiones in veram Praxim curandæ Tertianæ propositam à Doctore Petro Barba;" *ibid.* 1642. "Antimus Coningius Peruviani pulveris defensor, repulsus à Melippo Protymo;" *ibid.* 1655. Coningius is the assumed name of Honoratus Fabri; Protymus was that assumed by Plempius in order to decry the use of cinchona. "Avicennæ Canonis Liber primus et secundus ex Arabica Lingua in Latinam translatus;" *ibid.* 1658. "Tractatus de Affectuum Pilorum et Unguium;" *ibid.* 1662. "De Togatorum Valetudine tuendâ Commentarius;" Brux. 1670. The two following are generally ascribed to this author, though Mangetus and Lipenius (probably misinterpreting the initial) ascribe them to Francis Plempius; *viz.* "Munitio Fundamentorum Medicinæ V. F. Plempii adversus Jacobum Primerosium;" Amst. 1659. "Loimographia, five, Tractatus de Peste;" *ibid.* 1664. Eloy Dict. Hist. de la Medecine.

PLENARTY, in *Law*, a term used in ecclesiastical matters, to denote that a benefice is full, or possessed of an incumbent.

In which sense it stands opposed to *vacancy*.

Institution, by six months, is a good plenarty against a common person, but not against the king, without induction. See INSTITUTION and INDUCTION.

PLENARY, formed of the Latin *plenarius*, of *plenus*, full, something complete, or full. Thus we say, the pope grants plenary indulgences, *i. e.* full and entire remissions of the penalties due to all sins.

PLENE ADMINISTRAVIT, in *Law*, is a plea pleaded by an executor or administrator, where they have administered the deceased's estate faithfully and justly before the action brought against them. On *plene administravit*, pleaded by an executor, if it be proved that he hath goods in his hands which were the testator's, he may give in evidence, that he hath paid to the value of his own money, and need not plead it specially; for when an executor before the action hath paid the money in equal degree with that demanded by the plaintiff, he may plead fully administered generally, and give the special matter in evidence. 2 Lill. Abr. 330.

PLENEUF, in *Geography*, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brieuc; 20 miles W.N.W. of Dinan. The place contains 1243, and the canton 6502 inhabitants, on a territory of 115 kilometres, in 5 communes.

PLENILUNIUM, compounded of *plenus*, and *luna*, in *Astronomy*, that phasis or state of the moon, properly called the full moon.

PLENIPOTENTIARY, compounded of *plenus*, full, and *potentia*, power, a person who has full power and commission to do any thing.

The word is chiefly understood of the ministers or ambassadors sent from princes or states to treat of peace, marriages, and other important matters.

The first thing done in conferences of peace, is, to examine the power of the plenipotentiaries. See TREATY.

PLENITUDE, PLENITUDO, the quality of a thing that is full, or that fills another.

In physic, it is chiefly used for a redundancy of blood and humours.

Physicians reckon two kinds of plenitude. The one called *ad vires*, when the abundance of the blood oppresses the patient's strength.

The other *ad vasa*, when it fills the vessels too much; swelling them to a degree of bursting.

PLENNA, a word used by some writers to express any mucous humour.

PLENUM, in *Physics*, a term used to signify that state of things, in which every part of space, or extension, is supposed to be full of matter. It is used in opposition to a *vacuum*, which is a space supposed devoid of all matter.

The Cartesians adhere firmly to the doctrine of an absolute plenum. This they do on this principle, that the essence of matter consists in extension; and hence, indeed, the consequence is very easy, that wherever there is space or extension, there is also matter. But this principle we have elsewhere shewn to be false; and, therefore, the consequence drawn from it falls to the ground. See MATTER.

That there is a real vacuum, in the nature of things, is likewise demonstrated by arguments *à posteriori*, under VACUUM.

PLEONASM, PLEONASMUS, formed from *πλεονασμος*, *q. d.* superabundancy, in *Rhetoric*, a figure of speech, by which we make use of words, seemingly needless or superfluous, in order to express a thought with the greater force and energy.

Such is, *I saw it with my own eyes; or, he heard it with his own ears, &c.*

The pleonasm is called by the Latins *redundantia*.

Pleonasm, by grammarians, is usually defined a fault in discourse, wherein we say more than is necessary.

M. Vaugelas will not allow the phrase, *I saw it with my own eyes*, to be a pleonasm; inasmuch as there are no superfluous words in it; none but what are necessary to give a stronger assurance of the thing affirmed. It is sufficient that one of the phrases say somewhat more than the other, to avoid the imputation of a pleonasm.

In effect, though we give the name pleonasm to any thing that is not necessary, or that enters the discourse independently of the sense or construction, yet there are frequently words which, in that view, would be pertinent, and even are used to good purpose, to give a greater force or grace to discourse, and to ascertain the truth of what is said.

He spoke with his mouth, is a pleonasm in English; it is none in Latin: Virgil says, *sic ore locutus*. Some French authors deny *unir ensemble, to unite together*, to be a pleonasm.

PLEROSIS, a word used by the old Greeks to express the repletion or restoring the body to its natural state, after it has been emaciated by sickness.

PLEROTICS, Πληρωτικά, formed from *πληρωω*, *I fill*, in *Medicine*, a kind of remedies, otherwise called *incarnatives*, and *sarcotics*.

PLES, in *Geography*, a town of Russia, in the government of Kostrom, on the Volga; 16 miles S. of Kostrom. N. lat. 57° 15'. E. long. 41° 14'.

PLESHY,

PLESHY, a village and parish, situated in the hundred of Dunmow, and county of Essex, England, though now containing, according to the parliamentary returns of 1811, only 46 houses, and 221 inhabitants, was a place of distinguished consequence in ancient times. Gough and Morant are both of opinion that it was the site of a Roman station, from the number of urns and Roman bricks which have been dug up here, and from the boldness and regularity of the entrenchment surrounding the village. The vallum of this work is still very perfect on three sides, and appears to have had four original entrances through it into the inclosed area. These circumstances, however, though plausible reasons for assigning to Pleshy a Roman origin, are not conclusive evidence. In the Saxon era no mention is made of this place; indeed its authentic history does not commence till the reign of king Stephen, when we are informed that it was vested in the crown by the king's marriage with Maud, granddaughter of Eustace, earl of Boulogne, by whom it is probable the castle here was first erected. Stephen granted it to William de Magnaville, high constable of England, who procured licence to fortify the castle from Henry II. Hence we conjecture that he was the person who constructed the fosse, as well as the immense keep, which remains to this day a proud monument of the ancient grandeur and strength of this once majestic fortrefs. The keep is oval shaped, and measures about 890 feet in circumference, and forty-five paces in breadth at the top.

Humphrey de Bohun, earl of Hereford, having succeeded to the estate and honours of the Magnavilles, obtained leave of Edward I. to enlarge his park at Pleshy, by inclosing 150 additional acres. In this family the castle and manor continued till the year 1372, when Thomas of Woodstock, afterwards duke of Gloucester, became possessed of them, and of the dignity of high constable, by his marriage with Eleanor, eldest daughter, and co-heiress of Humphrey, the last male heir of the Bohuns. This nobleman, whose busy life and tragical fate form conspicuous features in the history of England, was decoyed from the castle by his nephew, king Richard II., and treacherously put to death. Pleshy, after that event, devolved to Edmund, earl of Stafford, in right of Anne, the duke's daughter. It afterwards fell to the crown, and was annexed to the duchy of Lancaster. From that period the castle seems to have been totally neglected, but the date of its demolition is not mentioned. Leland says that this place was anciently called Tumblestoun, and that Pleshy is a corruption for Castell de Placeto. A college for a master and eight secular priests, two clerks, and two choristers, was founded here by Thomas of Woodstock in 1393. The original endowments were subsequently augmented by various benefactors: and at the time of the dissolutions its revenues were valued at 139*l.* 3*s.* 10*d.* per annum clear. This house was granted by Henry VIII. to sir John Gates, who razed all the old buildings, the college-church excepted, which he however also partly destroyed. It continued in a ruinous state till the beginning of the last century, when bishop Compton, having been promoted to the see of London, repaired such portions of it as were standing, and added a neat body of brick. The principal monuments here are those of sir William Jolliffe, knt., and his nephew, Samuel Tuffnell, esq., whose family here possessed the manor for upwards of half a century. Some memorial of the former consequence of Pleshy appears in the election of a mayor annually from among the freeholders of the village, at the court-leet for the manor. This custom is singular, and seems to indicate that Pleshy was at one time a corporate town. Beauties of England and Wales, vol. v., by John Britton and E. W. Brayley,

from Morant's "History, &c. of Essex," folio; and Gough's "History and Antiquities of Pleshy," 4to.

PLESMONE, a word used by the ancients to signify plenitude or satiety.

PLESSEVITZA, in *Geography*, a mountain of Croatia; 12 miles N.W. of Bihacs.

PLESSOW, a town of the duchy of Warsaw; 8 miles W. of Kalisch.

PLESTIN, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Lannion; 7 miles S.W. of Lannion. The place contains 4862, and the canton 9460 inhabitants, on a territory of 105 kilometres, in 7 communes.

PLESUR, a river of the Grisons, which runs into the Rhine at Coire.

PLESZ, or **PLESSE**, a town and fortress of Silesia, and capital of a lordship, in the principality of Ratibor, on the borders of Poland, surrounded with walls, flanked with towers, and containing two churches; 17 miles N.N.E. of Teschen. N. lat. 49° 57'. E. long. 18° 56'.

PLETCHBERG, a mountain of Switzerland, in the canton of Berne; 22 miles S.S.E. of Thun.

PLETHORA, πλεθώρα, in *Medicine*, from πλεθω, *impleo*, fullness of habit, or an abundance of blood.

Every increase of the fluids is sometimes called plethora; but the medical authors who speak definitely, limit the term to a superabundance of good blood. (See Van Swieten, Comment. ad Aph. 106.) This, then, is scarcely to be considered as itself a disease, but a degree of high health, bordering upon disease; a condition which predisposes to disease, and renders the person liable to be disordered by any exciting cause, by which the equilibrium of the circulation may be accidentally disturbed.

The mechanical physicians ascribed many of the morbid actions of the system to plethora; and they remarked, that an abundance of blood was inconvenient to the animal economy in a relative manner only, in different cases, *viz.* relative to the quantity, to the space occupied, to the bulk, and to the patient's strength. The first, plethora *ad molem*, or *ad vasa*, signified the absolute over-abundance of blood, as seen by the florid distention of the minute vessels, and detected by a full, oppressed, and labouring pulse. This occurs generally in vigorous constitutions, where the digestive powers are strong and active, and the waste from exercise disproportioned to the supply. The second, or plethora *ad spatium*, is produced when, the quantity of the circulating fluids remaining the same, the capacity of the vessels is diminished; as may be exemplified in the state of the circulation in cold weather, or in the cold fit of fevers. The third, or plethora *ad volumen*, implies the contrary condition, or that in which, the quantity remaining the same, the bulk is augmented, as by external heat, inflammatory diseases, stimulating food and drink, violent passions, &c. The blood, however, is not capable of much expansion; and both this and the preceding condition are occasioned rather by a change in the distribution of the blood, than by any actual variation in its condition. By cold, it is driven from the extreme vessels to those of the interior; by heat, it is admitted into the relaxed vessels of the external parts. The last, or plethora *ad vires*, signifies only a comparative weakness of the circulating powers; so that although the quantity of blood be not superabundant, yet it is greater than the vessels are enabled to distribute freely.

After all these refinements of pathology, it will be obvious that there is, in fact, but one kind of actual plethora, which is a real superabundance of blood, and is therefore the cause of a predisposition to disease, especially to fevers,

to all inflammatory affections, such as gout and pleurisy, to apoplexy, lethargy, palsy, and the rupture of blood-vessels. This plethoric state is produced by a vigorous digestive power in the stomach, especially in certain constitutions, which possess a lax texture of the venous system; and its production is favoured by taking copiously of food that is nutritious and easy of digestion, by quietness and composure of mind, by much sleep, and by indolence and inactivity as to muscular exertion. (See CORPULENCE.) The symptoms by which the existence of this plethoric state are indicated, are thus enumerated by Van Swieten: we know that it is present, he says, if there be a great redness over the whole body, especially where the cuticle is fine and delicate, as in the corners of the eyes, the inside of the eyelids, nose, mouth, lips, and throat; if the veins are distended, and the pulse at the same time is full and strong; and if upon unusual motion, or exposure to heat, or taking of wine, a sense of fullness and distention is felt throughout the body, and this is followed by dullness and drowsiness. Comment. loc. cit.

The cure of this plethoric state is not always easy. Blood-letting is attended with temporary relief; but it is apt to be followed by an increase of the fullness, if other circumstances are not attended to. But with it should be combined a system of diet, more cooling and spare, and of less nutritious substances, of regularity and freedom in the relaxation of the bowels, and a gradual attainment of the power of corporeal exertion, by taking exercise at first by way of gestation, and subsequently by the more active use of the muscles, even by bodily labour, if that prove requisite.

PLETHRON, a Grecian measure, by some said to contain 1444, by others 10,000 square feet. Arbuthnot.

PLETTENBERG, in *Geography*, a town of Germany, in the county of Mark, on the Elbe and the Oester, governed by its own magistracy. The parish-church belongs in common to the Lutherans and Calvinists. The inhabitants are employed partly in agriculture and breeding of cattle, and partly in the manufacture of coarse cloths and smith's work, particularly scythes; beside other handicrafts; 28 miles S. of Hamm.

PLETTENBERG'S Bay, a bay on the S.E. coast of Africa. Cape Seal, at the southern extremity of the bay, is in S. lat. $34^{\circ} 6'$. E. long. $23^{\circ} 48'$. Variation of the compass $27^{\circ} 12'$ W. The tide flows at full or change $3^h 10^m$, and rises or falls five or six feet perpendicular. This bay scarcely seems capable, by any expence, of being rendered secure, even for small craft, in the winter months; but, in the summer season, ships may remain without any danger. Westward of this bay, at the distance of about eighteen miles, is *Kayna*, which see. Plettenberg's bay is a division of the district of Zwellendam, which begins at the Kayman's river, and continues to the inaccessible forests of Sitikamma. The whole of this tract of country is very beautiful, agreeably diversified by hill and dale, and lofty forests. Within seven miles of the bay are large timber-trees, and the surface is almost as level as a bowling-green, over which the several roads are carried. The peasantry who inhabit this district are mostly wood-cutters, who earn a very hard subsistence. The great distance from the Cape of Good Hope, being 400 miles of bad road, allows them little profit on a load of timber, when sold at the dearest rate in the Cape market, so that they prefer disposing of it at the bay for a mere trifle. Plank of thirteen or fourteen inches in width, and an inch thick, may be purchased on the spot at the rate of *3d.* per foot in length. The bark of several of the creeping plants in the forest might be employed as substitutes for hemp; and the iron ores, near the base of the mountain, might be worked

by clearing away the wood, of which there is an inexhaustible supply. Barrow's Africa, vol. ii.

PLETZDORF, a town of Bavaria, in the bishopric of Bamberg; six miles W.N.W. of Burg Eberach.

PLETZKY, a town of Saxony; two miles W. of Gommern.

PLEVEN, a town of European Turkey, in Bulgaria, on the Vid; 28 miles S. of Nicopoli.

PLEUGLIA, a town of European Turkey, in Servia; 40 miles W. of Jembafar.

PLEVIN, PLEVINA, in *Law*, a warrant or assurance, the same with pledge. See PLEDGE, REPLEVIN, &c.

PLEUMANGAT, in *Geography*, a town of France, in the department of the North Coasts; 13 miles S.S.W. of Dinan.

PLEUMARTIN, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Chatellerault. The place contains 1205, and the canton 7143 inhabitants, on a territory of 280 kilometres, in 12 communes.

PLEUMAUDAN, a town of France, in the department of the North Coasts; six miles S.S.W. of Dinan.

PLEUNOS, a town of Africa, in Barea. N. lat. $31^{\circ} 40'$. E. long. $25^{\circ} 20'$.

PLEURA, in *Anatomy*, the serous membrane, which lines the cavity of the thorax. See LUNG.

PLEURISY, PLEURITIS, in *Medicine*, an inflammation of the pleura, or membrane surrounding the lungs.

The pleurisy has been generally distinguished by medical writers from the peripneumony, or inflammation of the substance of the lungs; by the greater acuteness of the pain in the side, increased on inspiration, the greater hardness and strength of the pulse, the dryness of the cough, and the greater violence of the fever. It is in fact, however, only a modification of the same disease with the peripneumony; whence Dr. Cullen gave the same generic name *pneumonia* to both. We shall, therefore, refer the reader to the former article, where all the modifications of pneumonic inflammation are discussed at length. See PERIPNEUMONY.

PLEURITIS, the pleurisy.

PLEUROCYSTUS, in *Natural History*, the name of one of the general arrangements of the echini marini.

The word is derived from the Greek *πλευρον*, the side, and *κυστις*, the anus.

The echini of this division are distinguished from the others, by having their anus neither on the summit, nor in any part of the base, but in some part of the superficies of one of the sides.

PLEURODYNE, in *Medicine*, from *pleura* and *δύνη*, pain, signifies a pain of the side, independent of inflammation, as *pleuritis* denotes the pain arising from inflammation.

A stitch or pain in the side often occurs, independently of any acute inflammation of the lungs, pleura, or contiguous organs, and it is generally increased by the action of breathing. It has been often denominated a false or *spurious pleurisy*. The pain, however, is seldom seated in the membrane called the pleura, but often in the muscles of the chest, sometimes in the other membranous parts; and it may arise from rheumatism affecting those parts, from spasm or cramp, from a plethoric condition, or from a nervous and hysterical state, in which the circulation is languid and irregular: it may also be connected with a gouty, syphilitic, or scorbutic habit. Sauvages has distributed the pleurodyne into eighteen species, according to its origin from one or other of these causes. (See his Nosol. Method. class v. gen. ii.) The term is now most commonly applied to rheumatic pains affecting the muscles of the ribs and the diaphragm. See RHEUMATISM.

PLEURON, in *Ancient Geography*, the name of two towns

towns in Ætolia, the *Old* and the *New*; the former situated near Calyon, and the latter near mount Aracynthus.

PLEURONECTES, in *Ichthyology*, a genus of fishes of the order Thoracici, of which the generic character is; head small; eyes spherical, both on the same side of the head, and near each other; mouth arched; jaws unequal, toothed; gill-membrane with from four to seven rays; the cover generally of three laminæ; the body is convex and coloured above; flat and paler beneath; the vent is nearer the head.

This genus, which consists of about thirty species, comprehends those which are denominated flat-fish. The structure of this fish is considered as one of the most curious deviations from the general uniformity or regularity observed by nature in the external figure of animals, in which, with a few exceptions, both sides of the body are perfectly similar: but in the genus *Pleuronectes*, the animal is so constituted, that one side appears to represent the back, and the opposite side the abdomen. They swim obliquely or on their sides, and the two eyes are always placed on one side, and it is from this circumstance that the sections into which the species are divided, are constituted; that is, according as the eyes are on the right or the left side. The fish of this genus reside at or near the bottom of the water, owing to their having no air-bladder: they often bury themselves in the sand as far as the head, by which means they escape the jaws of the more rapacious tribes; the eyes are covered with a nictitant membrane; the nostrils are double and contiguous; the belly is without ribs; the fins are soft, and mostly with simple rays; the ventral and pectoral long, the tail generally rounded, with bifid rays.

A. Eyes both on the right Side of the Head.

TRICHODACTYLUS. Body rough; pectoral fins filiform. This is only known from the description of Artedi, who says that it is rough, of a grey colour, with dusky variations. It is a native of the Indian seas, and found about Amboina.

ZEBRA. Body with numerous transverse bands. This is reckoned a very elegant species, and readily distinguishable by its colours, the upper part being white, with a brownish cast towards the back, and marked from head to tail by numerous, double, deep brown, transverse bands, passing across the fins themselves. It is rather larger than the common sole. It is a native of the Indian seas, and in considerable esteem as an article of food.

PLAGIUSA. Body oblong, somewhat rough; dorsal and anal fins joined to the tail. It inhabits Carolina; the body is pale and cinereous.

OCCELLATUS. Body with four dark brown ocellate spots; the irids are white. Found in the sea about Surinam.

* **HIPPGLOSSUS**; Holibut. The body of this species is perfectly smooth; the tail is lunate. This species not only exceeds in size all the rest of the present genus, but may be considered as one of the largest of fishes, properly so called, having been found of the weight of three or four hundred pounds. It is a native of the Mediterranean and Northern seas, but appears to arrive at its greatest size in the latter; it is the most voracious of the whole tribe, preying on a variety of other fishes, as well as upon different kinds of crabs, shell-fish, &c. It is of a longer or more slender form than most other flat-fish. It is not much regarded as an article of food.

CYNOGLOSSUS. Body oblong, smooth; teeth obtuse; tail a little rounded. It is extremely allied to the preceding, and has been regarded rather as a variety than a distinct species.

It is a native of the Northern seas, and found in considerable numbers in deep bays about the coasts of Greenland.

* **PLATESSA**; Plaife. Body smooth; behind the left eye there is a row of six tubercles reaching to the lateral line. The plaife is easily distinguished from the others of the genus by its shape and colours, being very broad and flat; of a fine palish brown above, marked both on the body and fins by pretty numerous orange-coloured spots; the under side is white. It is an inhabitant of the Mediterranean, the Baltic, and Northern seas, and is found in considerable plenty about our own coasts. The flesh is very good, especially of those that run to a large size.

* **FLESSUS**; Flounder. Lateral line rough; short spines on the right side of the fins. The flounder is an inhabitant of the same seas as those in which the plaife is found. It is extremely common about our own coasts, and frequents our rivers at a considerable distance from the salt waters; it is in considerable esteem as food, and great quantities are brought to the London markets.

* **ROSEUS**; Rose-coloured Flounder. Body rosy; fins pale yellow-brown. It is frequently taken in the Thames.

* **LIMANDA**; Dab. Scales very small, ciliate; spinules at the root of the dorsal and anal fins with obtuse teeth. It inhabits the European seas; is less and thinner than the flounder; feeds on worms and insects, especially small crabs; it spawns in June; the flesh is reckoned very good.

* **LEVIS**; Smear-dab. Brown, with obscure yellow spots, beneath white, with five large dusky spots; scales smooth; the dorsal fin has seventy-nine rays. It is about eighteen inches long, and the flesh is reckoned good for food.

LIMANDOIDES. Body oblong, rough; lateral line straight, broad. It is found in the Northern seas; it resembles the plaife; the flesh is very good.

SOLEA; Sole. Body oblong, rough; the upper jaw is longer. The sole is an inhabitant of the Northern, Baltic, Mediterranean, and American seas, and grows to the length of two feet or more, and to the weight of six or eight pounds; its general size is, however, very much smaller. It is covered with small rough scales of an oblong form, each terminated by numerous spines, and very strongly fastened to the skin. These scales, from the elegance of their structure, have long since formed objects for the microscope; an erroneous idea sometimes prevails that the spiny end of the scale is that by which it is inserted into the skin. This fish delights in lying at the bottom of the coasts which it frequents, preying on small shell-fish, spawn, sea-insects, &c.: it is generally taken by the trawl-net. The chief fishery is said to be at Brixham, in Torbay.

* **ARNOGLOSSUS**; Smooth Sole. Thin, pellucid, white, smooth. It is found, though but seldom, on the coasts of Cornwall.

LINGUATULA. Vent on the left side; the teeth are very sharp.

GLACIALIS. Very smooth; above brown, beneath white; middle rays of the dorsal and anal fins rough, with small spines. It inhabits sandy places in the Frozen sea, and is about nine inches long.

PLATESSOIDES. Body above with brown spots. It inhabits sandy places in the mouths of rivers in Greenland; it is scarcely a foot long; feeds on small worms and fish; in *shape* it resembles the *R. linguatula*; in its *scales*, the sole; and in its *spots*, the plaife.

B. Eyes both on the left Side of the Head.

LINEATUS. Body rough, barred with black; it has no pectoral fins. It inhabits North America.

BILINEATUS.

BILINEATUS. Lateral line double, and also without pectoral fins. It is a native of China.

PUNCTATUS. Body broad and very rough. It inhabits the deep sandy places of the Northern sea. It is reckoned a great delicacy in Denmark.

***RHOMBUS;** Pearl. Body smooth. It is found in European seas, and is the broadest of its size, except the turbot; the body is covered with small scales, deep brown, with dirty yellow spots, beneath white; the flesh is very good, but inferior to the turbot described below.

DENTATUS. Body oblong, smooth; teeth extending out of the mouth. It inhabits Carolina.

***MAXIMUS;** the Turbot. Body rough. This fine fish, so highly prized by epicures, inhabits the European and Mediterranean seas: grows sometimes to thirty pounds weight; it is very voracious, and feeds on insects, worms, and testaceous animals; the body is squarer than any other species; it is covered with obtuse, unequal, spinous tubercles; above it is brown, varied with yellow; beneath it is white, spotted with brown; the flesh is firm and excellent. For the method of catching turbot, see the article **TURBOT.**

***PASSER;** Whiff. Lateral line much curved, prickly. It is a native of European seas, and is about a foot long; the flesh is good.

PAPILLOSUS. Lateral line curved; body papillous. It inhabits America, and is supposed to be a variety of the last.

MANCUS. Head tuberculate; pectoral fins unequal. It inhabits the sandy bottoms of the Brasil and Pacific seas.

ARGUS. Body variegated; tail rounded; jaws equal. It is found in the neighbourhood of the Caribbee islands; the body is covered with small soft scales, and variegated with yellow spots, which are dotted with brown, and edged with blue; the body is sprinkled with brown points.

LUNATUS. Body with scattered, blue, half ocellate spots. It is a native of the North American seas; the tail is lunate.

JAPONICUS. Tongue rough. It is a native of the Japan seas. It is about six inches long; the colour is brownish above, and whitish beneath; rays of the dorsal and anal fin so extremely numerous as to be counted with difficulty.

PLEURO-PERIPNEUMONY, or **PLEURO-PNEUMONY,** in *Medicine*, a term employed to denote the most common form of pulmonary inflammation, in which both the pleura and the lungs are involved in the disease at the same time. See **PERIPNEUMONY.**

PLEURORTHNOPŒA, a term used by medical writers to express that kind of pleurisy in which the patient cannot breathe, unless in an erect posture.

PLEUROTHALLIS, in *Botany*, from *πλευρα*, the side, and *θαλλος*, a bough or frond, apparently in allusion to the lateral insertion of the inflorescence, the whole plant often consisting of but a simple leaf with its stalk; and at the side, where both unite, the flowers are produced.—Brown MSS. Ait. Hort. Kew. v. 5. 211. — Class and order, *Gynandria Monogynia*. Nat. Ord. *Orchideæ*.

Ess. Ch. Lip of the nectary connected, by a joint, with the base of the column. Two lower calyx-leaves combined underneath. Masses of pollen two, without a furrow. *Br.*

1. *P. ruscifolia.* Butcher's-broom leaved Pleurothallis. (*Dendrobium ruscifolium;* Swartz *Orchid.* 94. Willd. *Sp. Pl.* v. 4. 135. *Epidendrum ruscifolium;* Jacq. *Amer.* 226. t. 133. f. 3. Linn. *Sp. Pl.* 1353. *Helleborine ruscifoliae* folio; Plum. *IC.* 171. t. 176. f. 2.)—Stem elongated. Leaf solitary, ovato-lanceolate. Flowers aggregate, at the base of the leaf.—Native of woods in the West Indies. It flowers in the stove in May and June. The pe-

rennial roots consist of numerous long simple fibres, growing parasitically on the branches or stems of trees. *Plants* several, about a span high, forming a tuft, like small lilies of the valley, but the flowers are not much elevated. Their form we have not had an opportunity of seeing.—We presume the two other species in Plumier's tab. 176, belong to the same genus; but the above is alone mentioned in Hort. Kew.

PLEURS, PLURS, or *Piuro*, in *Geography*, a town of Switzerland, which was formerly large and flourishing, and subject, as well as Chiavenna, to the Grisons. It is said to have contained three churches, many large houses, and a stone bridge over the Maria, and that its population amounted to at least 1500 inhabitants, who carried on no inconsiderable commerce. But it was totally overwhelmed by the fall of mount Conto, which terrible catastrophe happened on the 25th of August, 1618. The valley in which it was situated is very narrow, and the whole town was buried in one undistinguished ruin. A contemporary account relates, that the cloud of dust and rubbish was so great as to cover the heavens like smoke, and even to extend as far as Chiavenna; the inhabitants of which place, alarmed at the phenomenon, were still more terrified at the sudden disappearance of the river Maria, the course of which was stopped by the fallen fragments of rock, and apprehensive that the torrent had undermined Chiavenna, they precipitately fled in great numbers to the mountains. A part of the ancient walls, and the ruins of a country house, belonging to the richest family in the place, are the only remains of its former existence.

PLEURUIT, a town of France, in the department of the Ille and Villaine, and chief place of a canton, in the district of St. Malo. The place contains 6596, and the canton 10,973 inhabitants, on a territory of 75 kilometres, in 4 communes.

PLEUVAULT, a town of France, in the department of the Côte d'Or; 12 miles S.E. of Dijon.

PLEXUS, in *Anatomy*, a term applied to various parts of the body, and particularly where several nerves or blood-vessels are united together. The plexus choroides is situated in the lateral ventricle of the brain. (See **BRAIN**.) The plexus pampiniformis is made up of the ramifications and unions of the spermatic vessels. (See **GENERATION**.) In the nervous system plexuses are frequent, particularly in the great sympathetic. See **NERVOUS System.**

PLEYBEN, in *Geography*, a town of France, in the department of Finisterre, and chief place of a canton, in the district of Chateaulin; five miles N.E. of it. The place contains 3972, and the canton 14,404 inhabitants, on a territory of 375 kilometres, in 9 communes.

PLEYBERG, a town of the duchy of Carinthia, formerly called "Auffenstein;" 20 miles E. of Clagenfurt.

PLIANT *Mealy Tree*, in *Gardening*, a common tree in plantations. See **VIBURNUM.**

PLICA, in *Medicine*, commonly mentioned with the epithet *Polonica*, because the disease is endemic in Poland, and the neighbouring countries, is an affection of the hair, which becomes matted together, and thickened, so as to form masses which cannot be unravelled, in consequence of the deposition of a morbid matter in and about the hair.

The disease is called *Koltum*, or *Koltek*, in Poland; and by the Germans *Weichsel-zopff*, on account of its prevalence in the region watered by the Weichsel, or Vistula. Sauvages and the nosologists have denominated it *Trichoma*. As the disease is never seen in this country, except by the accidental visit of a person affected with it from the country

where it prevails, we can only describe it after the writers who have witnessed it. The most clear and concise account of it is given by M. de la Fontaine, surgeon at Warfaw, in his surgical and medical treatises on various subjects respecting Poland, published in German, from which we shall extract the following history.

The symptoms which precede the morbid affection of the hair are very various, and often put on the appearance of other diseases. Thus pseudo-rheumatic pains are sometimes the antecedents of the malady: and it is said that apoplexy, mania, and various nervous diseases are apt to occur, as well as inflammations, particularly of the eyes, indurations of the glands, gangrene, and caries, more particularly of the nasal bones and cranium. Sometimes, however, the *plica* comes on without any previous symptom, even in the course of one night; and violent passions of the mind, especially rage and terror, are said to have caused it instantaneously. The most common symptoms of its approach are, a sense of weight and torpidity in all the limbs, pains in the back, giddiness, difficulty of breathing, ringing in the ears, with an increased secretion of cerumen, dull pains in the orbits of the eyes and lacrymal glands, with an augmented flow of tears, head-ache, violent itching and prickling in the hairy scalp, pain in the præcordia, and depression of spirits. In many patients there is a remarkable change in the appetite, a craving for spirituous liquors, and for new and strange kinds of food, while they loathe the things which they used to relish most. But the most certain signs that a *plica* will soon be formed, are clammy sweats about the head, with a diminution of pains, and a sensation of tightness, as if the upper parts of the head were drawn together.

The hairs now begin to grow greasy, and emit a remarkably disagreeable smell. The patient has frequent alternations of shivering and heat, and feels an unpleasant prickling cold under his nails. Under these circumstances, a sort of crisis takes place, upon the deposition of the morbid matter upon the hair and nails, and the symptoms of ill health immediately disappear, except in some rare cases, where a new deposition is to take place, and the crisis is therefore imperfect. The matter is deposited in the hairs, and sometimes in greater quantity than they can contain; they then burst, and a prodigious quantity is poured out between them, glueing them together. It is not true, that the hairs extend so much that blood flows out of them, as has been affirmed, or that they bleed on being cut. Occasionally the matter is not only deposited in the hairy scalp, but upon the hair of the pubis, of the arm-pits, or upon the nails. If the symptoms continue, a second *plica* will certainly be formed, but not until the first has separated from the head, and new hair has grown: it is never certain, however, that a second will not be formed; for the disease often takes on a kind of periodic form. A constant sense of cold about the head, and particularly at the temples, is a sure sign of its returning.

Sometimes the whole matter is deposited in one half of the hair, the other half remaining sound: in which cases, the previous symptoms attack only one side of the body. The peculiar form of the matting depends upon the previous fashion of the hair: most of the men cut it short, while the women, on the contrary, have uncommonly long and beautiful hair. The morbid matter is first deposited in the rete Malpighii, from whence it penetrates into the hair, sometimes slowly, sometimes rapidly. The moisture oozing out from the hairs bind them so together, that it is impossible to separate them again: if the whole hair be affected, it forms a kind of cap; if it flow out more partially, several tails or rope-like *plicæ* are produced. Some

days after the mass of disease has been formed, it begins to emit an odour like that of rancid fat; and when it is touched, it excites a prickling unpleasent sensation in the fingers. M. Fontaine dissected a patient, in whom the *plica* had come on just before death, and he found the bulbs of the hair larger than natural, from which he pressed out a pale yellow clammy mucus. In another, in whom the *plica* was already old, he found nothing remarkable. The *plica* is apt to be productive of prodigious numbers of lice, from which the patient suffers even more than from the disease.

All writers have divided the *plica* into several species, according to the various forms which it assumes. Sauvages has described three species. 1. *Trichoma cirrosum*, or what the French call *plique en cordons*, is the most common form, when it appears in long tails or cords, as before mentioned. It was called absurdly enough by Schultz, *plica mas*, or the male *plica*. 2. *Trichoma villosum*, the *plica femina* of Schultz, when the disease is more generally diffused. And 3. The *Trichoma Polonicum*, when it suddenly extends to a great size, and forms a cap over the head. M. Alibert, in the treatise "Sur les Maladies de la Peau," which he is now conducting, has also divided the *plique* into three species, and points out several varieties under each. His first is *Plique multiforme*, or *Plica caput-medusæ*, which applies to the tail-like or serpentine agglutinations, which may not be inaptly compared to the fabulous head of Medusa. His second species is *Plique à queue, ou solitaire*, or *Plica longi-cauda*, in which the *plicæ* are not divided, as in the former species, but reunite and form one tail-like mass, not unlike the tail of a quadruped, often acquiring a great length. And his third is *Plique en masse*, or *Plica cæspitosa*, in which a conglomerated mass is formed over the head, without any tail-like divisions. These arbitrary classifications afford at least some distinct notion of the varieties of appearance which the disease assumes.

The proximate cause of the *plica*, according to M. de la Fontaine, is a peculiar morbid matter, which is clammy and acrid, has its seat in the lymph, and is deposited critically upon the hair or nails. When it is deposited upon the nails, either of the hands or the feet, they become larger, thicker, prominent, deformed, horny, and ill-coloured, but not black.

The exciting causes are altogether uncertain; for neither the air, water, nor food, seems to have any influence in producing it; nor are cleanliness and regular combing the hair any defence against it. Experience shews, however, that it is a contagious disease, and very often congenital; at the same time, those to whom it is communicated by contact are said to have it slightly, and to be easily cured. It spares no sex, age, or condition, nor even newly arrived strangers, and some infants bring it into the world with them: the lower classes of the people, however, suffer most from it; and those who have soft brown hair are most frequently affected, though no colour escapes. The *plica* is never white; but when it drops off in old people, it is sometimes succeeded by white hairs. Peles, who travel, are sometimes affected with it in other countries, and even their children. There is no accurate history of its origin: the Greeks, Romans, and Arabians have not mentioned the disease; but some modern writers affirm that it was imported from Tartary in the year 1387. It now prevails in Tartary, White and Red Russia, Lithuania, and from the source of the Vistula to the Carpathian mountains; but is more frequent in some districts than in others.

The method of cure recommended for *plica* varies with the circumstances of the case. When fever is present, moderate evacuations

evacuations must be referred to; but blood-letting is to be employed with great caution. M. de la Fontaine compares the disease with the small-pox, in which, when the febrile action is too feeble to produce the eruption, it must be increased; when it is too violent, it must be diminished. Hence the patient must be, in some instances, supported by generous diet; while, in others, a spare regimen must be adopted. In order to bring about the crisis, the same writer recommends the use of sudorifics, and appears, indeed, to consider antimony as a specific in this disease. The older physicians praise the lycopodium as possessed of specific powers, but without any good grounds; and the common people believe in a great number of specific remedies, but the disease has not become less frequent, notwithstanding these supposed means of cure. Mercurials, especially when carried to the extent of exciting salivation, are said to be highly detrimental in every case; but if the disease be complicated with syphilis, the corrosive muriate of mercury is very beneficial.

External remedies are almost always necessary; such as the application of warmth to the head, in the form of vapour, warm bath, or fomentations made with the decoctions of various plants: a decoction of soap is esteemed beneficial when the head-ache is severe. Sinapisms and blisters are likewise applied with advantage. The plica may, or may not, be cut off according to circumstances. After a complete crisis, it separates from the head, and remains attached only by found hair. This may take place in a few days, weeks, or months. If it has lost its peculiar smell and greasy appearance, has become dry, and all concomitant symptoms have ceased, it may be cut off by dividing the found hair: for it is remarkable, that even an old plica cannot be cut in the middle without giving pain. The new hair may be washed with warm water, and combed out. If, however, the plica be new, fit fast on the head, cause a prickling in the fingers when touched, and the general symptoms have not subsided, it must not on any account be cut off. The most dreadful accidents often immediately ensue from such practice. Some have become instantly blind, or have died from apoplexy, or in epileptic convulsions. The people are so much afraid of this, that they will seldom permit the plica to be cut off, even when it may be done with safety. If bad consequences follow the cutting off of the plica, the most certain and speedy remedy is to apply it in its former situation. This must be done before it becomes dry; and it is almost incredible, says M. de la Fontaine, that, after one, two, three, or more days, it will again adhere to the head. He does not maintain that it grows to the stumps of the hair; but that innumerable examples prove, that a kind of callus is formed, as in a fractured bone. If the plica be not brought to adhere again, the patient, if he survive, remains excessively sick, until the hair grow, and a new plica be formed. The Jews, who are bigotted to their own customs and methods of cure, never permit it to be cut off, and nothing can be more disgusting than one whose beard and whiskers are affected with this disease.

If the morbid matter be deposited on the surface of the body, it is said to occasion malignant and obstinate sores, which give a great deal of trouble. If it have a tendency to deposit itself in the nails, it must be encouraged by the application of stimulants, such as tincture of cantharides, blisters, or by touching a fresh plica with the fingers. The nails do not separate so readily as the hair, and can only be safely cut off when new nails have begun to grow; and this often does not happen. The Poles believe, that keeping their hair short; or even shaving the head, is a preservative

against this disease; but, on the contrary, the men suffer much more than the women, whose hair is long; and it at last affects the hair on other parts of the body.

M. de la Fontaine recommends a mild, attenuant, and corrective diet, as in other diseases proceeding from acrimony of the fluids, with the use of ripe fruits. The correctness of his advice, however, may be justly questioned, since he informs us, that the diet of the common people in Poland consists almost, if not entirely, of vegetables, which are generally made sour. He concludes by this singular observation, that, if all these means be inadequate to produce the crisis, *inoculation* of the disease will often effect it; and that this is performed by putting on a cap, which has just been worn by one who has a recent plica. See Duncan's *Annals of Medicine*, vol. i. sect. 1. Haller, *Disputationes Med.* tom. i. art. 16, 17. Alibert, *Précis Theorique et Pratique sur les Maladies de la Peau*, p. 92, et seq. *Memoirs of the Literary and Philosophical Society of Manchester*, vol. iv. part 2.

PLICA, Lat. a pleat, a fold, a wrinkle, the name of a musical character in the first time-table that was formed. It was a kind of ligature, or retardation (*signum morositas*, says de Muris); it served for a series of notes in passing from one sound to another by regular degrees from a semitone to a 5th ascending, and descending: it was of four kinds: 1. The long plica ascending, a square figure with one single stroke or tail ascending, . 2. The long plica descending has two strokes or tails, one longer than the other, . 3. The short plica ascending has a single tail on the left side turned up, . The 4th plica has a single tail on the left side descending, .

PLICARIA, in *Botany*, a name used by some for the club-moss.

PLICATED LEAF. See LEAF.

PLIGHT, in our old *Law Books*, a term which signifies the estate, with the quality of the land; though sometimes it extends also to the rent-charge, and the possibility of a dower. *Coke's Inst.* fol. 221.

PLINIA, in *Botany*, so named by Plumier, in memory of the famous Roman naturalist; see PLINY. *Plum.* Gen. 9. t. 11. *Linn. Gen.* 270. *Schreb.* 337. *Willd.* Sp. Pl. v. 2. 998. *Mart. Mill. Dict.* v. 3. *Juss.* 342. *Lamarck Illustr.* t. 428.—Class and order, *Icosandria Monogynia*. *Nat. Ord. Hesperideae*, *Linn. Rosaceae affine*, *Juss.*

Gen. Ch. *Cal.* Perianth inferior, small, of one leaf, flat, in five acute reflexed segments. *Cor.* Petals five, ovate, concave, widely spreading. *Stam.* Filaments twenty, inserted into the calyx, capillary, longer than the corolla; anthers globose. *Pist.* Germen superior, roundish; style awl-shaped, wavy; stigma simple. *Peric.* Drupa globose, furrowed, of one cell. *Seed.* Nut solitary, large, ovate, rough, cloven at the summit.

Eff. Ch. Calyx in five segments. Petals five. Drupa superior, furrowed. Nut rough.

Obf. Every botanist, who has attended, in any manner, to the subject, is aware of the great obscurity that envelops this genus, which depends chiefly on the authority of Plumier, and which no succeeding botanist has been able to verify; except perhaps Allamand, from whose communications Linnæus corrected the generic character as above. Some have supposed Plumier to have been totally mistaken, as to the germen being superior, and that *Plinia* is no other than

than an *Eugenia*. Linnæus, and Allamand possibly, founded these genera in their ideas; for their *P. rubra* is, as every body knows, *Eugenia uniflora*. See Willd. Sp. Pl. v. 2. 962, where its multifarious synonyms are correctly stated; see also our article EUGENIA. We subjoin all we can find upon record of the original and only species of *Plinia*, of which we have never been so fortunate as to see a specimen.

1. *P. crocea*. Orange-fruited *Plinia*. Linn. Mant. 244. Willd. n. 1. (*P. pinnata*; Linn. Sp. Pl. ed. 1. 516. ed. 2. 735. *P. pentapetala*; Linn. Mant. 402. *P. fructu croceo, odorato*; Plum. Ic. 219. t. 225.) By Plumier's figure, which is our only guide, this appears to be a tree, with round alternate branches. The leaves are opposite, nearly sessile, ovate, pointed, entire, about three inches long and one broad, apparently smooth, with one rib, and many transverse incurved veins. Flowers scattered over the larger branches, nearly sessile, solitary, scarcely so big as a hawthorn blossom, the tapering style projecting beyond the numerous stamens, which are themselves longer than the petals. Fruit globular, saffron-coloured and fragrant, according to Plumier, the size of a large gooseberry, deeply furrowed and wrinkled. Nut more slightly furrowed, or rather quite globular and only striated, large, with a thin shell, and full kernel.

Burmah, the editor of Plumier, misconceived the leaves to be abruptly pinnate, taking the whole branch for a leaf. Linnæus adopted this error, and having once made a false step, he floundered deeper and deeper in trying to correct himself, altering the specific name time after time, and contracting the plant with one of a different genus; into which last mistake he was indeed led by his correspondent Allamand. We do not presume to throw any new light on this obscure point of botanical history, but what we have collected may serve to assist those who may be so fortunate as to meet, in some part of the West Indies or of South America, with the plant Plumier described. Dr. Swartz, who investigated the former with great industry, seems never to have seen the *Plinia*; nor has he, in his *Observations Botanica*, 203, done more than indicate the generic confusion, to which we have sufficiently adverted.

PLINIA, in *Gardening*, comprises a plant of the exotic shrubby kind for the stove, of which the species cultivated is the red-fruited *plinia*, or myrtle (*P. pedunculata*.)

Method of Culture.—It is increased by the seeds, which should be procured from abroad, and which should be sown in pots, filled with rich mould, plunging them in a bark hot-bed, when they appear in the same season. They may also be increased by planting cuttings of the young shoots, in the later spring and summer months, in pots filled with good earth, covering them with hand or bell-glasses, and watering them occasionally. They may be so rooted as to be fit for removing into separate pots the same year.

It is a plant highly ornamental in stove collections, from its flowering in the winter season.

PLINIANA, in *Geography*, a town or rather village of Italy, in the department of the Lario; six miles N. of Como. This place is remarkable for a singular fountain, which is still to be seen in the same state as described by Pliny, lib. iv. ep. 30. This spring bursts from a rock, and falls in natural cascades into the lake of Como. It ebbs and flows three times a day; gradually rising until it forms a considerable stream, and then as gradually subsiding till it becomes almost dry.

PLINLIMMON, a mountain of Wales, in the N. part of the county of Cardigan, on the borders of Montgomeryshire.

PLINTH, from *πλαθός*, brick, in *Architecture*, a flat square member, in form of a brick: sometimes, also, called the slipper.

The plinth is used as the foot, or foundation of columns: being that flat square table, under the mouldings of the base and pedestal, at the bottom of the whole order; seeming to have been originally intended to keep the bottom of the primitive wooden pillars from rotting.

The plinth is also called the *orle* or *orlo*.

Vitruvius also calls the Tuscan abacus, plinth, from its resembling a square brick.

PLINTH of a *Statue*, &c. is a base or stand, either flat, round, or square, serving to support a statue, &c.

PLINTH of a *Wall*, is a term for two or three rows of bricks advancing out from the wall; or in the general for any flat high moulding, serving in a front wall to mark the floors; or to sustain the eaves of a wall, and the larmier of a chimney.

PLINTHITIS, a kind of alum found in some of the islands of the Archipelago, and called also *placius*, from its usually being found in thin cakes.

PLINTHIUM, a name given by the ancients to a machine invented for the making extension of dislocated or fractured limbs. Oribasius describes several kinds.

PLINY, the elder, CAIUS PLINIUS SECUNDUS, in *Biography*, a distinguished Roman writer, was born, it is thought, at Verona, in the reign of Tiberius, A.D. 23. He was descended from an illustrious family, and served in the army during the wars in Germany. He rose to various public employments under the emperors Nero, Vespasian, and Titus. It is said that there is scarcely a man of business who was so devoted to study, or comprehended such an extent of literary research. The following is the mode of his spending his time at Rome, when he was high in the possession of the imperial favour. Before day-break he waited upon Vespasian, who was also an early riser, and then proceeded to execute the emperor's orders. On returning home he employed the rest of the day in study. After taking a light repast, he reclined in the sun according to the Roman custom, while a book was read to him, from which he took notes. He never perused any work without making extracts, as he was accustomed to say "that no book was so bad as not to afford something valuable." He then bathed, slumbered a little, and rising fresh, as if to a new day, studied till supper time. Even during that repast a reader was at his side, as there was upon all his journeys; and a vacant hour never occurred which he did not employ in reading and writing. Of his avarice of time, his nephew, the younger Pliny, gives the following instance: one of his friends having obliged the reader to repeat something that he had pronounced improperly, "Did you understand him?" said Pliny, "I did," he replied. "Why then did you stop him? We have lost more than ten lines by the interruption." He always went from place to place in a sedan, that he might read on his road, and reproved his nephew for walking as so much time lost. The plan thus adopted by the philosopher, it might be supposed, would have precluded all original observation and reflection; but he was diligent in natural pursuits, and it was his ardent curiosity and thirst of knowledge that occasioned his death. He had the command of the fleet stationed at Misenum, when, in the month of August, A.D. 79, a great eruption of Vesuvius broke out. On its first appearance he steered directly to the spot, as well for the humane purpose of giving assistance to the fugitives, as for viewing the progress of the eruption. The volcano raged with the utmost fury, and spread alarm through all the vicinity. While others were flying he ordered his pilot

pilot to steer directly across to Stabiae, where his friend Pomponianus had a villa. He there landed, and passed the night in the house. In the mean time showers of ashes almost blocked up his apartments, while the walls were shaken with an earthquake, and towards the morning it appeared necessary to quit the place. In his flight he was suffocated, being then in the 56th year of his age, high in reputation and dignity, and in great esteem with the emperor Titus. His works are as follow; "On the Use of the Javelin on Horfeback;" "On the Life of Pomponius Secundus;" "Of the Wars in Germany," in twenty books; "On Oratory," three books; "On Grammar," eight books; "On the History of his own Times," thirty-one books; "On Natural History," thirty-seven books. Of all these works, that on natural history is the only one that has come down to our times, and it is regarded as one of the most valuable relics of classical antiquity. The editions of this work were very numerous at an early period, and many learned men have employed their talents in correcting the text. Har-douin was supposed to be one of the most successful as well as industrious editors. His edition, in five volumes 4to., Par. 1685, was superior to any at that time published. He has been succeeded by others, and in 1779, Brotier gave a new edition at Paris, in six vols. 12mo., which is much esteemed.

PLINY, the younger, C. PLINIUS CÆCILIUS SECUNDUS, born at Como, in the reign of Nero, A.D. 62, was the son of L. Cæcilius, by a sister of the elder Pliny. He was sent to Rome for education, and after perfecting himself in the Greek language, he was placed under the tuition of Quintilian and Nicetes. His disposition and talents caused him to be adopted by his uncle Pliny, and destined to be the heir of his name and fortune. He was in the eighteenth year of his age when the eruption of mount Vesuvius took place, which proved fatal to his uncle. He had imbibed so much of his uncle's ardour for study, that he chose to remain reading the history of Livy, rather than accompany his uncle to a nearer view of the interesting but fatal phenomenon. He began to plead causes soon after his uncle's death, but his labours in this way were soon interrupted by a campaign into Syria, with the rank of military tribune. He did not, however, wholly abandon his literary pursuits in that situation, but availed himself of the presence of the philosophers Euphrates and Artemidorus, who had been banished Rome, with the other professors of philosophy, by Vespasian. After his return his reputation for eloquence stood so high, that when he was likely to harangue the people, vast crowds attended, and he was sure to be greeted with the loudest applauses, in which even the judges sometimes joined. In the reign of Domitian he was raised successively to the offices of quaestor, tribune of the people, and praetor. Under Nerva he was appointed to the office of prefect of the Saturnian treasury. In the third consulate of the emperor Trajan, Pliny was one of the honorary consuls termed *suffecti*, and on this occasion he returned public thanks to the emperor in an oration, which he afterwards enlarged to the panegyric of Trajan. After this the care of the channel, and the banks of the Tiber, was next conferred upon him, with the augurate; and then he was appointed proconsul; whence he wrote to Trajan that curious letter concerning the primitive Christians, which is extant among his epistles. Pliny's letter is esteemed as almost the only genuine monument of ecclesiastical antiquity, relating to the times immediately succeeding the apostles, it having been written within about forty years after the death of the apostle Paul. It has been preserved by Christians themselves, as a clear and unsuspecting evidence of the purity of their doctrine and practice,

and is frequently appealed to by the early writers of the church against the unprovoked calumnies of their adversaries. It is not known what became of Pliny after his return from Bithynia; antiquity is also silent as to the time of his death; but it is conjectured, that he died either a little before or soon after Trajan; that is, about the year 116.

It appears that he lost his first wife in the beginning of Nerva's reign, and that soon after he married his beloved Calphurnia: he never had any children. He was one of the greatest wits, and one of the worthiest men among the ancients. He had fine parts, which he cultivated with great care. He wrote and published a great number of pieces; but nothing has escaped the wreck of time except the books of Letters, and the panegyric upon Trajan. This has ever been regarded as a master-piece of excellent composition. It is an elaborate specimen of true eloquence, chiefly of value as containing enlarged views of the duties of a sovereign. Some writers have said, that no panegyrist was ever possessed of a finer subject, and on which he might better indulge in all the flow of eloquence, without incurring the suspicion of flattery and falsehood; but others observe, that as it was composed at the very beginning of Trajan's reign, it has but little weight as a testimony to the merits of that excellent emperor. It might perhaps have been the happy means of fixing his character, and it is no small praise if it produced this sort of effect, and that the youthful emperor was determined by a life of virtue to deserve all the encomia paid to him. His epistles, in ten books, are much to be prized for the anecdotes with which they abound, of the characters and incidents of the times, and likewise for the purity and elevation of their moral sentiments, which impress a favourable idea of the writer. They were no doubt intended for the public. Every epistle is a kind of historical sketch, in which we have a view of him in some striking attitude either of active or contemplative life. They strongly mark that love of applause which was unquestionably his ruling passion, and afford some curious facts relative to the modes of feeding a writer's vanity in those times. They exhibit the writer as a professed rhetorician, entertaining and perhaps wearying his friends with long and laboured orations and recitations, commanding constant plaudits by virtue of his rank, his wealth, and his truly estimable qualities; but he was probably in some instances the dupe of adulation. The best editions of Pliny the younger are the Variorum by Veenhuisius; and that by Longolius. His epistles have been translated into English by lord Orrery and Mr. Melmoth; the version of the latter is singularly elegant. Pliny contributed largely to the maintenance of a public professor for the instruction of youth in the place of his nativity; assigned an annual revenue for the support of children of both sexes, whose parents had been reduced to poverty; and founded a public library.

PLISA, in *Geography*, a town of Lithuania, in the palatinate of Minsk; 21 miles E. of Minsk.

PLITE of *Lauren*, in our *Old Writers*, seems to be an ancient measure, as a yard or ell, at this time: it is mentioned in the stat. 3 Ed. IV. cap. 5.

PLIVA, in *Geography*, a river of Bosnia, which runs into the Verbas.

PLIUSA, a river of Russia, which runs into the Baltic, between Nerva and Ivangorod.

PLIUSKINA a town of Russia, in the government of Irkutsk; 20 miles N.E. of Verchnei-Udinsk.

PLIWISCHEN, a town of Prussia, in the province of Samland; 28 miles E. of Königsberg.

PLOCAMA, in *Botany*, so named by Dr. Solander, from πλοκαμος, a head of hair, in allusion to its long pendulous

dulous entangled branches.—Ait. Hort. Kew. ed. 1. v. 3. 508. ed. 2. v. 2. 63. Schreb. 797. Willd. Sp. Pl. v. 1. 1210. Mart. Mill. Dict. v. 3.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceae*, Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, minute, five-toothed, permanent. Cor. of one petal, bell-shaped, in five deep oblong segments. Stam. Filaments five, short, inserted into the tube; anthers linear, erect, somewhat incumbent. Pist. Germen inferior, globose; style thread-shaped, swelling upwards, longer than the stamens; stigma obtuse, undivided. Peric. Berry nearly globose, of three cells. Seeds solitary, linear-oblong.

Ess. Ch. Calyx superior, with five teeth. Corolla bell-shaped, five-cleft. Berry of three cells. Seeds solitary.

1. *P. pendula*. Drooping Plocama. Ait. n. 1. Willd. n. 1.—Native of the Canary islands, from which country it was sent to Kew by Mr. Masson in 1779; and of the Cape of Good Hope, from whence we have a specimen communicated by Mr. Lambert. It is, or was, kept in the greenhouse at Kew; but no time of flowering being mentioned, the plant is perhaps now lost, without having ever been figured, or fully described. The stem is shrubby, erect, two or three feet high, roundish, smooth, with generally alternate branches, of which the uppermost are extremely numerous, drooping or pendulous, slender, obscurely quadrangular, roughish, leafy. Leaves opposite, on short stalks, linear, acute, entire, very narrow, smooth, somewhat fleshy. Stipulas small, acute, between the footstalks, permanent, and at length forming a narrow ring, round each joint of the stem or branch. Flowers terminal, axillary, or from the upper forks of the branches, small, on short, simple, roughish stalks, either solitary, or two or three together. Berry not half the size of a currant. The whole plant, except the old stem, turns black in drying.

PLOCE, in *Rhetoric*, a figure by which a word is repeated, by way of emphasis; in such manner, as not only to express the subject, but some particular character or property of it.

Cruelty! yes, cruelty beyond all example. His wife's a wife indeed! So Cicero says, Young Cato wants experience, but yet he is Cato.

PLOCKEN-ALBEN, in *Geography*, a mountain of Carinthia; six miles S.E. of Mauten.

PLOCZKO, or PLOZK, a town of the duchy of Warsaw, late of Poland, and capital of a palatinate of the same name in Masovia, situated on an eminence near the Vistula: the see of a bishop, suffragan to the archbishop of Gnesna. It is also the residence of a palatine, a castellan, and a starosta; and contains several churches richly ornamented, one of which is the cathedral. The provost or dean is sovereign of the nobility who reside here, and is accordingly styled prince of that territory. In the castle is a gymnasium or seminary. The provincial court of judicature is held in this town: and a good trade is carried on by its inhabitants; 64 miles W.N.W. of Warsaw. N. lat. 52° 17'. E. long. 19° 35'.

PLOEMUR, a town of France, in the department of the Morbihan; two miles W. of L'Orient.

PLOEN, or PLOX, a town of the duchy of Holstein, which has several times been destroyed by fire; 23 miles N.N.W. of Lubeck. N. lat. 54° 10'. E. long. 10° 22'.

PLOERMEL, a town of France, and principal place of a district, in the department of the Morbihan. The place contains 4512, and the canton 11,800 inhabitants, on a territory of 207½ kilometres, in six communes. N. lat. 47° 40'. W. long. 2° 59'.

PLOESTI, a town of Walachia; 200 miles E. of Belgrade.

PLOEUC, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brieuc; 10 miles S. of St. Brieuc. The place contains 5073, and the canton 12,800 inhabitants, on a territory of 170 kilometres, in six communes.

PLOGASTEL, a town of France, in the department of Finisterre, and chief place of a canton, in the district of Quimper; seven miles W. of Quimper. The place contains 1047, and the canton 10,809 inhabitants, on a territory of 230 kilometres, in 13 communes.

PLOK-PENIN, in *Commerce*, a term used in the public sales at Amsterdam for a little sum given by the last bidder.

The plok-penin is a kind of earnest, by which it is signified, that the commodity is adjudged to him.

The plok-penin differs according to the quality of the commodity, and the price of the lot. Sometimes it is arbitrary, and depends on the pleasure of the buyer; and, sometimes, it is regulated by the ordinances of the burgo-masters.

PLOMBIERES, in *Geography*, a town of France, in the department of the Vosges, and chief place of a canton, in the district of Remiremont; six miles S.W. of Remiremont. The place contains 1109, and the canton 9947 inhabitants, on a territory of 215 kilometres, in six communes.

PLOMNITZ, a town of Silesia, in the county of Glatz; two miles N.W. of Habelschwerdt.

PLOMO, in *Metallurgy*, a name given by the Spaniards, who have the care of the silver mines, to the ore of that metal, when it is found adhering to the surface of stones, and incrusting their cracks and cavities in the form of small and loose grains of gunpowder. Though these grains be but few in number, and the rest of the stone have no silver in it, yet they are always very happy in meeting with it, as it is a certain token that there is a very rich vein somewhere in the neighbourhood. And if in digging forwards they still meet with these grains, or the plomo in greater quantity, it is a certain sign that they are getting more and more near the good vein.

PLONCOUR, in *Geography*, a town of France, in the department of the Finisterre; eight miles S.W. of Quimper.

PLONE, a river of Pomerania, which runs into the Dammisch see, at Damme.

PLONEVEZ de Faou, a town of France, in the department of the Finisterre; eight miles W. of Carhaix.

PLONGEON, in *Ornithology*. See COLYMBUS.

PLONKETS, in our *Old Writers*, a kind of coarse wool-len cloth. 1 Ric. III. cap. 8.

PLONSK, in *Geography*, a town of the duchy of Warsaw; 22 miles N. of Ploczko.

PLOSAWO, a town of Poland, in the palatinate of Belcz; 28 miles W.S.W. of Belcz.

PLOSS, a town of Germany, in the principality of Culmbach; six miles N.W. of Bayreuth.

PLOT, ROBERT, in *Biography*, a natural philosopher and antiquary, was born, in 1641, at Borden, near Sitting-bourn, in Kent. He was educated at Magdalen Hall, Oxford, where he took his degree of L.L.D. in 1671. Soon after this he became distinguished for his zeal in philosophical and natural science, and was made a fellow of the newly constituted Royal Society, of which learned body he was elected one of the secretaries in 1682. In the following year he was appointed the first keeper of Ashmole's museum at Oxford, and at the same time professor of chemistry in the university. Antiquities were the leading objects of his pursuit, and in 1687 he was made register to the earl marshal's court, and in 1695 the Mowbray-herald extraordinary.

nary. He died in 1696. He is principally known in the literary world by his two county natural histories, which were the first of the kind published in England, and were exemplifications of a great plan which he had formed for a natural history of the whole kingdom. The "Natural History of Oxfordshire" was published first in 1677, and again in 1705, with additions and corrections by Mr. Burman. That of "Staffordshire" was published in 1679, and reprinted in 1686. It was decorated with views of the seats of the nobility and gentry. It is at present extremely scarce. Both these county histories include not only all that properly belongs to the natural history, but whatever relates to arts, manners, and antiquities, and all other memorabilia. As secretary to the Royal Society, he conducted the publication of their Transactions from N^o 143 to 166 inclusive, and he communicated to it some papers of his own. Since his death two letters of Dr. Plot's have been published relative to antiquities in Kent and Thetford. He left a number of manuscripts, among which were large collections for a natural history of Kent. Biog. Brit.

PLOT, or Plott, in Gardening. See GRASS-PLAT, &c.

PLOT, in Dramatic Poetry, the fable of a tragedy or comedy; or the action represented therein.

PLOT is more particularly used for the knot or intrigue which makes the difficulty and embarrass of a piece.

The unravelling puts an end to the plot.

PLOT, in Surveying, the plan or draught of any parcel of ground, *e. gr.* a field, farm, or manor, surveyed with an instrument, and laid down in the proper figure and dimensions. See PLOTTING.

PLOTILE, in Geography, a town of Samogitia; 25 miles N.N.W. of Miedniki.

PLOTINOPOLIS, in Ancient Geography, a town of Thrace, upon the river Hebrus; 22 miles from Trajanopolis, according to the Itinerary of Antonine.

PLOTINUS, in Biography, a Platonic philosopher, was born at Lycopolis, a city of Egypt, in or about the year 204. In very early life he began to shew a great singularity both in taste and manners. He began to study philosophy at about the age of twenty, and for some time he attended the lectures of different famous professors, who then abounded in Alexandria, but he was dissatisfied with all their systems, and attached himself to Ammonius, who attempted to reconcile the different opinions then subsisting among the philosophers, and founded a distinct eclectic school, in which he taught his disciples certain sublime doctrines, and mystical practices, which he communicated to them under a solemn injunction of secrecy. With the instructions of such a preceptor, Plotinus, whose mind had a strong tincture of enthusiasm, was highly delighted, and he told his friend, that he had now met with a tutor in all respects suited to his wishes. Under this master he prosecuted his philosophical studies during eleven years, and became a deep proficient in the abstruse subtleties, and mystical flights of his system. Upon the death of Ammonius, he determined to travel into Persia and India, to learn wisdom of the Magi and Gymnosophists. In this resolution he was encouraged by the example of Apollonius Tyaneus, whose pretensions to the magic arts were said to be derived from these sources. For some time Plotinus considered himself to be under an obligation not to disclose the doctrines which he had learned in the school of Ammonius, in consequence of the injunction of secrecy to which he had submitted, but two of his fellow-pupils having publicly taught the mysteries of their master, he thought himself absolved from his engagement, and became a lecturer in philosophy upon eclectic

Vol. XXVII.

principles. During ten years he confined himself to oral discourse, but at length he found it necessary, as well for the convenience of his pupils, as for himself, to commit the substance of what he delivered to writing. The novelty of his plan of instruction drew after him a crowd of auditors, among whom were persons of high rank of both sexes. To the instructions of those who were willing to become his auditors he devoted himself with the greatest ardour and assiduity. He frequently prepared himself for his sublime contemplations by watching and fasting; hence his enthusiastic passions were sometimes raised to such a pitch, that he believed he was under the immediate protection of a genius, or familiar spirit, of the most eminent order, who was not merely a dæmon, but a god. The superiority which he fancied belonged to his tutelary genius, inflated him with a degree of pride, that bordered upon impiety, or perhaps insanity. He, however, enjoyed so high a reputation for wisdom and integrity, that many private quarrels were referred to his arbitration, and several persons of both sexes, when upon their death beds, sent for him to take upon him the care of their estates, and the guardianship of their children. Such offices he never refused, and he discharged them in a manner that gave the highest satisfaction to the parties concerned. His excellent character secured to him the esteem of many persons of high rank, and particularly of the emperor Gallienus, and his empress Salonina. The romantic turn of his mind was sufficiently shewn, by the use which he made of his interest at court. (See PLATONOPOLIS.) He died in the year 270, when he was in the 66th year of his age. When he found his end approaching, he said to Eustochius, "the divine principle within me is now hastening to unite with that divine being which animates the universe;" expressing by these words a leading principle of his philosophy, that the human soul is an emanation from the divine nature, and will return to the source whence it proceeded. By his disciple and biographer, Porphyry, he is represented as having possessed the power of working miracles: this was probably said with a view of depreciating the Christian religion, of which Porphyry was a great enemy. The treatises of Plotinus, which are fifty-four in number, were distributed by his biographer under six classes, called Euneads. Proclus wrote commentaries upon them. At the request of Cosmo de Medici, Marsilius Ficinus made a Latin version of them, which was first published at Florence, under the title of "Plotini Opera ex interpret. Marsilii Ficini, cum commentariis, necnon Vita Plotini à Porphyrio conscripta 1492." The Greek text was afterwards published at Basil, from a manuscript stated by Lambecci to be in the Imperial library, accompanied with the version of Ficinus in 1580. Dr. Enfield, in his abridgment, &c. of Brucker's Phil., speaking of Plotinus, says "that he made it the main scope and end of his life to dazzle his own mind, and the minds of others, with the meteors of enthusiasm, rather than illuminate them with the clear and steady rays of truth. How much is to be regretted that such a man should have become, in a great degree, the preceptor of the world, and should, by means of his disciples, have every where disseminated a species of false philosophy, which was compounded of superstition, enthusiasm, and imposture. The muddy waters sent forth from this polluted spring, were spread through the most celebrated seats of learning, and were even permitted to mingle with the pure stream of Christian doctrine. Not only at Rome, where Plotinus taught, but first in Alexandria, and afterwards in many of the principalities of Asia Minor, and even at Athens, the ancient seat of wisdom, the system of Am-

monius and Plotinus was embraced and propagated by men, who, in learning and abilities, were greatly superior to its founders." Enfield's Hist. Phil.

PLOTTING, among *Surveyors*, the art of describing or laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, or the like instrument, and a chain.

In surveying with the plain-table, the plotting is needless; the several angles and distances being laid down on the spot as fast as they are taken.

But in working with the theodolite, semicircle, or circumferentor, the angles are taken in degrees; and the distances in chains and links. So that there remains a subsequent operation, to reduce those numbers into lines; and so to form a draught, plan, or map. The operation is called *plotting*.

Plotting, then, is performed by means of two instruments, the protractor and plotting-scale. By the first, the several angles observed in the field with a theodolite, or the like, and entered down in degrees in the field-book, are protracted on paper in their just quantity.

By the latter, the several distances measured with the chain, and entered down, in like manner, in the field-book, are laid down in their just proportion.

Under the articles **PROTRACTOR** and **PLOTTING-scale**, is found, severally, the use of those respective instruments in the laying down of angles and distances; we shall here give their use conjointly, in the plotting of a field, surveyed either with the circumferentor, or theodolite.

PLOTTING, Method of, from the circumferentor. Suppose an inclosure, *e. gr.* A B C D E F G H K (*Plate VI. Surveying, fig. 10.*) to have been surveyed: and the several angles, as taken by a circumferentor in going round the field, and the distances, as measured by a chain, to be found entered in the field-book, as in the following table.

	Deg.	Min.	Cha.	Link.
A	191	00	10	75
B	297	00	6	83
C	216	30	7	82
D	325	00	6	96
E	12	24	9	71
F	324	30	7	54
G	98	30	7	54
H	71	00	7	78
K	161	30	8	22

1. On a paper of the proper dimensions, as L M N O (*Plate VI. Surveying, fig. 11.*) draw a number of parallel and equidistant lines, representing meridians, expressed in dotted lines. Their use is, to direct the position of the protractor; the diameter of which must always be laid either upon one of them, or parallel thereto; the semicircular limb downwards for angles greater than 180°, and upwards for those less than 180°.

The paper being thus prepared, assume a point on some meridian, as A, whereon lay the centre of the protractor, and the diameter along the line. Consult the field-book for the first angle, *i. e.* for the degree cut by the needle at A, which the table gives you 191°.

Now since 191° is more than a semicircle or 180°, the semicircle of the protractor is to be laid downwards; where, keeping it to the point with the protracting pin, make a mark against 191°; through which mark, from A, draw an indefinite line A b.

The first angle thus protracted, again consult the book for the length of the first line A B. This you find ten

chains 75 links. From a convenient scale therefore, on the plotting-scale, take the extent of 10 chains 75 links between the compasses; and setting one point in A, mark where the other falls in the line A b, which suppose in B: draw, therefore, the full line A B for the first side of the inclosure.

Proceed then to the second angle; and laying the centre of the protractor on the point B, with the diameter as before directed, make a mark, as c, against 297°, the degrees cut at B; and draw the indefinite line B c. On this line, from the plotting-scale, as before, set off the length of your second line, *viz.* 6 chains 83 links; which extending from B to the point C, draw the line B C for the second side.

Proceed now to the third angle or station; lay then the centre of the protractor, as before, on the point C; make a mark, as d, against the number of degrees, cut at C, *viz.* 216° 30': draw the indefinite line C d, and thereon set off the third distance, *viz.* 7 chains 82 links; which terminating, *e. gr.* at D, draw the full line C D for the third side.

Proceed now to the fourth angle D: and, laying the centre of the protractor over the point D, against 325°, the degree cut by the needle, make a mark e; draw the occult line D e, and thereon set off the distance 6 chains 96 links; which terminating E, draw D E for the fourth line: and proceed to the fifth angle, *viz.* E.

Here the degrees, cut by the needle, being 12° 24' (which is less than a semicircle), the centre of the protractor must be laid on the point E, and the diameter on the meridian, with the semicircular limb turned upwards. In this situation make a mark, as before, against the number of degrees, *viz.* 12° 24', cut by the needle at E; draw the line E f, on which set off the fifth distance, *viz.* 9 chains 71 links; which extending from E to F, draw the line E F for the fifth side of the inclosure.

After the same manner proceed orderly to the angles F, G, H, and K; then placing the protractor, making marks against the respective degrees, drawing indefinite lines, and setting off the respective distances, as above, you will have the plot of the whole inclosure, A B C, &c. Such is the general method of plotting from this instrument; but it must be observed, that in this process, the stationary lines, *i. e.* the lines in which the circumferentor is placed to take the angles, and in which the chain is run to measure the distances, are, properly, the lines here plotted. When, therefore, in surveying, the stationary lines are at any distance from the fence or boundaries of the field, &c. off-sets are taken, *i. e.* the distance of the fence from the stationary line is measured at each station; and even at intermediate places, if there prove any considerable bends in the fence.

In plotting, therefore, the stationary lines being laid down, as above, the off-sets must be laid down from them; *i. e.* perpendiculars of the proper lengths must be let fall at the proper places from the stationary lines. The extremes of which perpendiculars, being connected by lines, give the plot desired.

If, instead of going round the field, the angles and distances have been all taken from one station, the process of plotting is obvious, from the example above; all here required, being to protract, after the manner already described, the several angles and distances, taken from the same stationary point in the field; from the same point or centre on the paper. The extremities of the lines thus determined, being then connected by lines, will give the plot required.

If the field has been surveyed from two stations, the stationary

tionary lines are to be first plotted, as above; then the angles and distances taken from each to be laid down from each respectively.

PLOTTING, Method of, where the angles are taken by the theodolite, i. e. by back-sight and fore-sight (as it is called) is somewhat different. To prepare the angles for plotting, the quantity of each must first be found, by subtracting the degrees of the fore-sight and back-sight from each other: the remainder is then the angle to be protracted. The use of parallel lines is here excluded; and instead of laying the protractor constantly on, or parallel to meridians, its direction is varied at every angle. The practice is thus:

Suppose the former inclosure to have been surveyed with the theodolite, after the manner of back-sight and fore-sight; and suppose the quantity of each angle to be found by subtraction.

An indefinite line is drawn at random, as A K, (*fig. 11.*) and on this the measured distance, *e. gr.* 8 chains 22 links, is set off, as in the former example: if now the quantity of the angle A have been found 140° , the diameter of the protractor is to be laid on the line A K, with the centre over A; and against the number of degrees, *viz.* 140, a mark made, an indeterminate line drawn through it, and the distance of the line A B laid down from the scale upon it.

Thus we gain the point B; upon which laying the centre of the protractor, the diameter along the line A B, the angle B is protracted, by making a mark against its number of degrees, drawing an occult line, and setting off the distance B C, as before.

Then proceed to C, laying the diameter of the protractor on B C, the centre on C protracts the angle C, and draw the line C D: thus, proceeding orderly to all the angles and sides, you will have the plot of the whole inclosure A B C, &c. as before.

PLOTTING-Scale, a mathematical instrument usually of box-wood, sometimes of brass, ivory, or silver, and either a foot, or half a foot long, and about an inch and a half broad.

It is denominated from its use in plotting of grounds, &c.

On one side of the instrument (represented *Plate VI. Surveying, fig. 12.*) are seven several scales or lines, divided into equal parts. The first division of the first scale is subdivided into ten equal parts, to which is prefixed the number 10, signifying that ten of those subdivisions make an inch; or that the divisions of that scale are decimals of inches.

The first division of the second scale is likewise subdivided into 10, to which is prefixed the number 16, denoting that sixteen of those subdivisions make an inch. The first division of the third scale is subdivided in like manner into 10, to which is prefixed the number 20. To that of the fourth scale is prefixed the number 24; to that of the fifth, 30; that of the sixth, 40; and that of the seventh, 48; denoting the number of subdivisions equal to an inch, in each, respectively.

The two last scales are broken off before the end, to give room for two lines of chords, marked by the letters C C.

On the back-side of the instrument is a diagonal scale, the first of whose divisions, which is an inch long, if the scale be a foot, and half an inch, if half a foot, is subdivided, diagonally, into 100 equal parts; and at the other end of the scale is another diagonal subdivision, of half the length of the former, into the same number of parts, *viz.* 100

Next the scales, is a line divided into hundredth parts of a

foot, numbered 10, 20, 30, &c. and a line of inches subdivided into tenths, marked 1, 2, 3, &c.

PLOTTING-Scale, Use of the. 1. Any distance being measured by the chain, to lay it down on the paper.—Suppose the distance to be 6 chains 50 links. Draw an indefinite line; set one foot of the compasses at figure 6 on the scale, *e. gr.* the scale of 20 in an inch, and extend the other to five of the subdivisions, for the 50 links: this distance being transferred to the line, will exhibit the 6 chains 50 links, required.

If it be desired to have 6 chains 50 links, take up more or less space, take them off from a greater or lesser scale, *i. e.* from a scale that has more or fewer divisions in an inch.

To find the chains and links contained in a right line, as that just drawn, according to any scale, *e. gr.* that of 20 in an inch. Take the length of the line in the compasses, and applying it to the given scale, you will find it extend from the number 6 of the great divisions to five of the small ones; hence the given line contains 6 chains 50 links.

PLOTTING-Table, in *Surveying*, is used for a plain table, as improved by Mr. Beighton, who has obviated a good many inconveniences attending the use of the common plain table. See *Phil. Trans. N^o 461. sect. 1.*

PLOTTNITZ, in *Geography*, a lake of Silesia, in the principality of Oels; four miles E. of Militzsch.—Also, a town of Silesia, in the principality of Neisse; three miles W. of Patschkau.

PLOTUS, the *Darter*, in *Ornithology*, a genus of birds of the order Anseres. The generic character is, bill straight, pointed, toothed; the nostrils have a slit near the base; face and chin naked; legs short; all the toes are connected. The birds of this genus, of which there are three species, have a small head, and long slender neck; they are chiefly seen in southern climates; they live chiefly on fish, which they take by darting forwards the head while the neck is contracted like the body of a serpent.

Species.

ANHINGA; White-bellied Darter. The head is smooth, and the belly white. It inhabits Brazil, and is about 34 inches long. It builds on trees, and is hardly ever seen on the ground; when at rest it sits with the neck drawn in between the shoulders. The flesh, though sometimes eaten, is reckoned rancid and oily. The bill is cinereous, yellowish at the base; irids golden; head, neck, and breast reddish-grey; body above black, the scapular feathers with a white spot in the middle; it has 12 tail-feathers, which are broad and long; its legs are of a yellowish ash-colour.

MELANOGASTER; Black-bellied Darter. Head smooth; belly black. It is about three feet long, and found in Ceylon and Java. There are three varieties of this species. 1. Above brown, beneath black; streaks on the scapulars and oval spots on the wing-coverts white. Between the breast and belly is a rufous band. It is a native of Cayenne. 2. Black; back and scapulars spotted with white; wing-coverts yellowish-white; tail rufous at the tip. 3. Black; head, neck, and wing-coverts streaked with rufous and brown. It is found at Senegal.

SURINAMENSIS; Surinam Darter. Head crested; belly white. Found, as its name imports, in Surinam; is about 13 inches long, and is domesticated. It feeds on fish and insects, especially flies, which it catches with great dexterity.

PLOTZKAU, in *Geography*, a town of Germany, in the duchy of Anhalt-Bernburg; five miles S.S.W. of Bernburg.

PLOUAGAT, a town of France, in the department of

of the North Coasts, and chief place of a canton, in the district of Guingamp. The place contains 2034, and the canton 7239 inhabitants, on a territory of 172½ kilometres, in seven communes.

PLOUARET, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Lannion. The place contains 4276, and the canton 14,092 inhabitants, on a territory of 260 kilometres, in eight communes.

PLOUAY, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of L'orient; seven miles N. of Hennebon. The place contains 3586, and the canton 12,304 inhabitants, on a territory of 215 kilometres, in seven communes.

PLOUBALAY, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Dinan; nine miles N. of Dinan. The place contains 1385, and the canton 6008 inhabitants, on a territory of 92½ kilometres, in eight communes.

PLOUDALMAZEAU, a town of France, in the department of the Finistère, and chief place of a canton, in the district of Brest; 10 miles N.N.W. of Brest. The place contains 2899, and the canton 14,588 inhabitants, on a territory of 177½ kilometres, in 12 communes.

PLOUDERY, a town of France, in the department of the Finistère, and chief place of a canton, in the district of Brest; five miles E.N.E. of Landerneau.

PLOUESCAT, in *Geography*, a town of France, in the department of the Finistère, and chief place of a canton, in the district of Morlaix. The place contains 2138, and the canton 9648 inhabitants, on a territory of 125 kilometres, in five communes.

PLOUGH, in *Agriculture*, a well-known implement for breaking up the ground for tillage crops. It was invented at a very early period, being, perhaps, nearly coeval with the cultivation of the soil itself, as, without some kind of a plough, no produce of any consequence could possibly have been derived from the ground. It is an implement which was well known to the Egyptians, the Greeks, and the Romans, and which has prevailed in most of the Eastern countries for a vast number of ages.

These tools are constructed in different ways, according to the particular uses to which they are to be applied, and the nature of the land on which they are to be employed; as it is obvious that no one sort of plough can be made use of in all cases with equal success: differences in the nature of the soils, situations, and methods of performing the work, must necessarily require a diversity in their forms and modes of construction. Some of the more common and less complex kinds may, however, be very generally applied in the cultivation of land, and, of course, are the most useful on most sorts of arable farms. It is remarked in the Essex corrected report on agriculture, that "there is scarcely a circumstance in the agriculture of the kingdom more surprising, after so general attention has been paid to it, than the extreme uncertainty in which the true structure of the plough yet remains. That variations for different soils and circumstances must and ought to occur, is admitted; but one plough for one specific object might have been produced, its superiority to others ascertained, and the principles in its construction, on which such merit depended, fully developed, and laid down in accurate drawings; yet this has not been done; and the only approximation to it, it is contended, in a paper by the late Mr. Arbuthnot, which the writer published near forty years ago in his 'Eastern Tour.' Farming mechanics, it is supposed, look to the Board of Agriculture for supplying this great deficiency, which can be supplied only by a series of experiments, demanding a considerable expence, and more attention."

Ploughs may, with propriety, be divided into the *swing* and *wheel* kinds, the former being such as are wholly destitute of any sort of machinery that can produce resistance in the way of friction about the end of the beam. Those are of course the lightest of draught, but require the experience of a good ploughman in using them. But these sorts of ploughs vary much in different parts of the kingdom. When well made they are, however, very effective, and capable of being generally employed in the ploughing of the lighter sorts of land. And they have other advantages, which are those of not being so readily put out of order, and of affording less fatigue to the teams employed in drawing them.

Those of the latter sort are such as have the complex apparatus of wheels applied to them in some way or other, though they differ exceedingly in the manner in which this is done. From the steady manner in which these ploughs mostly proceed in their work, they are evidently capable of being managed by much less experienced ploughmen. It is suggested in the Middlesex Report, that wheels seem to have been added to ploughs in consequence of the want of expertness in the workmen; and that in all sorts of land, but especially in that of the stony and more stiff kind, they afford

afford much assistance, by enabling them to execute the work with greater regularity in the depth, and more evenness in the surface. But from the nature of the machinery with which they are loaded, they are evidently more expensive in their construction, more liable to be put out of order, and from the friction that is thus produced require more strength in the teams that are employed in drawing them. Besides, they have the disadvantage of being more apt to be put out of order in their course, by the occurrence of stones, clods, and other surface inequalities, than those of the former kind. An inconvenience attending these ploughs is also noticed by lord Somerville in the Communications to the Board of Agriculture, which is, that with *wheel-ploughs* workmen are apt to set the points of their shares too low, so as by their inclined direction to occasion a heavy pressure on the wheel which must proceed horizontally. Of course he conceives the effect of this struggle to be an increased weight of draught infinitely beyond what could be imagined, on which account he thinks that the wheel is to be considered as of no consequence in *setting a plough for work*; but that passing lightly over the surface it will be of material use in breaking old lays, or lands where flints, rocks, or the roots of trees are present, and in correcting the depression of the share from any sudden obstruction, as also in bringing it quickly into work again, when thrown out towards the surface. It is however believed on the whole, by the writer of the report just mentioned, that in comparing two extensive districts, one of which is managed with wheel-ploughs, and the other with those of the swing kind, taking every description of ploughmen that are met with in them, the wheel-ploughs will be found to have the advantage in point of neatness of work.

But the great weight of the carriage parts for the wheels, and the time and trouble which they require in adjusting and fixing them, are great objections to the use of this sort of plough in most cases, and particularly for the general purposes of husbandry.

Therefore, in the forming of all sorts of ploughs, the less they are encumbered with machinery of the wheel or other kinds, the more *useful they will probably be found*.

All around Kelvedon, in the county of Essex, it is stated in the agricultural survey of that district, that they make use of both swing or foot, and wheel-ploughs, and that it is much disputed which is preferable. In favour of the swing-plough, it is contended that it is better calculated for fallowing, as the soil can be broken up to a greater depth, and it does not rise at the headlands, which is the case with the wheel-plough; the ends of the furrows being shallower, from the wheels, as soon as they get upon the headlands, throwing the share up. The swing, or foot-plough, is easier of draught, the prime cost is less, and it is kept in repair at a smaller expence.

The wheel-plough, on the other hand, keeps a more regular depth, and will turn a shallower furrow, when the fallows are put upon the ridge, or formed into ridges; the work can be done with more regularity, the wheels being put out to the exact width at which furrows are to be made; this is of material consequence. And further, wheel-ploughs about the above place, can be worked when swing ones will choke on stubbles, and they are varied in *pitch* with more exactness, as well as go deeper than the others; but swing-ploughs are better, if the land be at all wet.

It may be noticed, however, that when the men are accustomed to ridge-ploughing, they will do it as well with the swing or foot-plough as with the wheel, but they cannot block up hard land in the summer so well with it.

And in respect to the depth of this sort of work, some contend that very deep ploughing can hardly be effected without the assistance of wheels to the ploughs. Besides, if the land is to be broken up for fallow late in the spring, and the soil comes up in large blocks, which is sometimes the case in wet land and late fallowing, the swing, or foot-plough, is apt to be thrown out of the furrow, and does not perform its work so well as the wheel-plough.

It is found a matter of great importance in the construction of the swing-plough, that the beam should have the length of about six feet, or six feet and a half. The rule or reason for which, according to Mr. Arbuthnot, is that the line of traction from the tug at the horse's shoulder to the centre of gravity and resistance, is a little behind the point of the share.

In the Rural Economy of Yorkshire, after noticing the similarity of the principles that are requisite in the construction of the ship and the plough, and considering the difficulty of fixing and reducing them to a regular theory, as nearly the same, it is observed, that the art of construction in either case is principally attained by practice. In this district, says the writer, the ploughs of different makers pass through the soil, with various degrees of facility and execution; nevertheless, though he has paid some attention to the different makes, he finds himself entirely incapable of laying down such particular rules of construction as would do his country any service, or his work any credit. Even the general principles of construction he must mention with diffidence.

The great difficulty in the construction of a plough is that of adapting it to all soils, in all seasons, and to all depths. If the soil break up in whole furrows, every inch of depth requires, in strictness, a separate plough, or a separate regulation. Here rests the main objection to the winding mould-board, which admits no regulation in respect of depth. If the semi-arch, or hollow of the hind part of the mould-board, be raised sufficiently high to turn a thick furrow completely, it is of no use in turning a thin one. On the contrary, if it be brought down sufficiently low to turn a shallow furrow properly, it is impossible to turn a deep one with it in a workman-like manner. There is not room for it within the hollow, or semi-archway of the mould-board. The inevitable effect of this is, either the furrow is forced away wholly by the upper edge of the mould-board, and set on edge; or the mould-board rides upon the furrow, raising the heel of the plough from the ground, the bad effects of which need not be explained. An upright stern, with a moveable heel-plate to turn the furrow at any given depth, is, in this point of view, much preferable to a hollow mould-board; and if its use in raising a crest of mould, for the purpose of covering the seed, be added, its preference is still more conspicuous. But some of these inconveniences have been obviated by the invention of moveable mould-plates, as will be seen afterwards.

Yet in the construction of all sorts of ploughs, there are, notwithstanding, a few points or circumstances that ought to be particularly, and in all cases attended to; such as the following: that part which perforates the soil, and breaks it up, and which is usually termed the *throat* or *breast*, should have that sort of clean, tapering, sharpened form, that is introduced with the greatest readiness, and which affords the smallest resistance in its passage through the ground. According to some, this part should be long and narrow, making an acute angle with the beam, as the length of the breast is supposed to have a tendency to preserve the *flag* from being broken, on account of the surface for its support being longer; which is a circumstance of consequence in the ploughing

PLOUGH.

ploughing of old lays for wheat, pease, and other similar crops; as, by such means, the growth of weeds through the broken ground is prevented. And the resistance of the earth against the breast is likewise lessened, in proportion to the acute angularity of that part against the beam of the plough. The mould-board should also have that sort of curved, twisted, or hollowed-out form, which is best calculated to lessen resistance, and at the same time give the furrow-slice the proper turn. And the beam and muzzle of these implements should likewise have such a construction, as that the team or moving power may be attached in the best and most suitable *line of draught*, as this is a circumstance of great importance, when several animals are made use of together, that the draught of the whole may coincide in the most perfect manner, and with the utmost exactness.

Likewise, in the construction of every sort of plough, much regard should be paid to the weight, so that they may have sufficient strength for the purpose, without being unnecessarily heavy. Much may be done in this intention, by lessening the quantity of wood in those parts where there is no particular stress, while it is retained so as to have full power in the others. This has been much less attended to in the making of ploughs than its importance would seem to demand.

It is noticed in the Agricultural Survey of the County of Essex, that the *throat* at the fore end or neb of the plate or breast in the Norfolk, and most other ploughs, with the exception of the Rotherham, rises from the upper surface of the share too perpendicularly, and too much at right angles to the line of friction, or pressure of the earth the plate has constantly to act against: working thus abruptly in the ground, the slice or furrow is violently torn, or burst from off the ground hard, broken and imperfectly turned over, instead of being gradually cut, raised whole, and whelmed over; as will always be the case, when the plough enters the ground obliquely, and at a proper angle; and that the plate or mould board is properly turned for raising up, and turning the slice completely over.

It is a clear position, proved by experiment, that a femi-ellipsis is the true form of throat which is necessary in ploughs, which is the part or space from the share point to the junction or approach of the breast to the beam: and that there is found a remarkable variation in the form of the *breasts*, or mould-boards of the ploughs throughout the northern parts of the same district, and which is chiefly in the degree of concavity or convexity. Some wheel-wrights and farmers prefer a form rather concave, a flatness in the fore part, which joins the share, and which gradually fills up as the sweep recedes; others like it neither concave nor convex; and there are many ploughs in which the convexity is extremely great.

The great length of the breast, in some ploughs, is a circumstance which gives steadiness to the implements; but, at the same time, it is probably the means of increasing the draught to the horses in a great degree.

The shortness of the breast, if the curve or sweep be in perfection, or wears equally every where, may lessen friction, and certainly does, if the earth be loose; but it probably may not have the same effect in the first earth, upon a stiff layer. It is, however, a pretty general opinion, that it lessens it in all cases.

A great variety of breasts, of different forms and constructions, are represented in the plates upon ploughs, in the Agricultural Survey already referred to, which are well worth consulting by the inquirer on this subject; and in the ploughs which are given here, there is also a very great di-

versity in the shape of the same part, as will be seen by attending to the figures of the different plates.

Some cultivators in this district use a breast which is very convex, and contend that such a degree of roundness and fullness in the bosom is necessary on heavy lands; also, that the soil sticks adhesively to the plough, if it be not thus rounded all the way; as well as that it turns the furrow better.

On the great variety of the breasts of ploughs, which appear in the plates of the above Survey, all of which are more or less distinct and different from each other, it is observed that they will all, on certain soils, and moments or times of tillage, make very good work; but it does not hence follow, that the form is a matter of indifference: such a conclusion would be very erroneous. There is a considerable difference between a breast passing freely through the soil without loading, and driving the earth before it, or pressing it after the furrow is turned, and another that has either of those faults, not visible perhaps in the work when finished, but to the great fatigue of the horses. In the construction of the plough, as has been already seen, there is not a point of more importance.

One of the most extraordinary circumstances in these breasts is, that of their all, with the exception of one, having more or less convexity, and in many, as has been seen, to a very extraordinary degree, especially in those about Birchholt and South-End. But in that furnished by his excellency Mr. Jefferson, the late president of the United States of America, and which was sent to the Board of Agriculture, and first tried by C. C. Weltern, esq., at Felix Hall in this district, the formation was made on the idea, that as the bottom cut of the furrow is, or ought to be, perfectly *flat*, the breast, which comes in direct contact with it, should be flat also; so that there should be no disposition in the mould to sink into any depression or concavity of the breast; nor any projection from a right line in the breast, to press or force into the furrow-slice, as it is turning. The idea is new and excellent: but what, on such principles, can be said to the convexity in some instances, the shape in the breasts of which must constantly have a tendency to *groove* that furrow-slice, from pressing in the centre. It should seem as if this must, on every principle, be erroneous. The retaining of it, in the case of Mr. Duckett's plough, is supposed, more apparently than really, an exception, in consequence of the soil he had to work on, as it was invented for a very loose sand only; and on such a soil the straight breast is much more admissible than on any other. This plough was seen at work on his farm many years ago, and it made excellent work: the convex *addition* to the flat surface, on the lower part, was probably made to divide the weight of the moving sand, and to keep enough of it in a due degree of elevation.

The objection to so much concavity or flatness in the fore part of the breast, as appears in that supplied by the American president, is that of the loose earth of the furrow *loading* there, which in some cases it is very apt to do.

Another point in which the ploughs here, as well as in other places, seem to be deficient, is in the height of the breast from the ground: they are, for the most part, too low behind; they should be, therefore, somewhat raised in this respect. In turning over a furrow of loose mould with rolling clods, the hind corner of the breast should be high enough to sweep them over, but without pressure.

In the next place, that part which is called the plough-heel may be examined, which comprises the position of the breast behind, and forms, together with the end of the *rest*, that wedge which fills up the furrow. There are two principal

PLOUGH.

cipal questions, it is supposed in this district, in relation to the form of it:—What ought to be the breadth at bottom, or, more properly speaking, the heel? and, what should be the breadth at top? Some think the heel should not be more than seven inches wide at bottom, which is the common width in some places. In examining the ploughs, in some cases, it appears that the breast closes at the heel gradually, being a termination of that convexity of breast, of which so many farmers in this district are fond. Improvements have been made, in which this narrowness at the heel has been retained, without the convexity *before*, and but slightly behind. Some ploughs are found to be faulty at the top of the breast behind: it overhangs the furrow too much, and seems to the eye to be in a position to *press*.

In concluding the subject, it is remarked, that when the ploughs in a single county can vary so much in the breast, or earth-board, and that in a district, too, not at all remarkable for diversity of soil, which might call for considerable variations, it must afford a strong proof how very undetermined the true mechanism of this most necessary of all tools still continues to be. And this, it is contended, ought to excite the endeavours of every scientific farmer to multiply experiments, to reduce the construction to plain and fixed principles.

In regard to the *pitch* of ploughs, it is noticed, that in the operation of working wheel-ploughs with improperly turned plates, or mould-boards, it will frequently happen, from the resistance produced against the plough by stones, the tenacity or compression of the earth, that they are obliged to be let down below the corresponding line of level, so materially necessary to the equal bearing between the pitch of the plough, and to the inclination which is thus given to the point of the share downwards, and which ought always to be, as nearly as possible, in a line drawn parallel to that of the draught, and with the breast-work, which forms the fulcrum for the beam to rest on. When a plough is so constructed, and set to work, that it bears unequally in these points, the end of the share will be rooting or digging with its point downwards, kicking up and sideways at the heel, and rendering it utterly impossible to plough the ground clean, or in anywise to lay the work uniform, or even in a tolerable manner; notwithstanding an excessive and unnecessary degree of labour is thereby produced to the ploughman and horses. This description is not so very clear, but there can be no doubt that not going close at the heel is a very common fault in wheel-ploughs, and often seen in Norfolk, as well as in other counties, in cases in the former, which have not the least reference to the breast; and it is a just observation, that the horses suffer much by it. The draught-chain in some ploughs, which draws by the hammer, between the coulter and the tuck, is not so parallel with the horizon as it would be, were it thrown more backward, which is the case in other tools of this kind, and forms a much better position.

In each of the above descriptions of ploughs there are several varieties in common use in different districts of the kingdom; but it is only necessary here to describe such as have been found to answer in the most perfect manner in practice.

In the *swinging* sort, those most in use are the *Rotherham* plough, which is a light useful plough for all the less heavy sorts of soil, and which, probably from its neat simple construction, is in more general use than any other, especially in all the more northern districts of the kingdom. It has certainly much superiority where one plough is only required, and where the advantageous and economical method of performing the work with one man and two horses without a driver is had recourse to. It is in much estimation in all the

West Riding of Yorkshire, and is said in the Survey of that district to have been invented by Mr. Joseph Foljambe, of Eastwood, about seventy years ago. As constructed in that part of the island, the dimensions are as follow:

	Feet.	Inch.	
From the end of stilt on land-side to the point of the share	7	4	}
From the end of beam where inserted into it to ditto, of ditto	3	0	
Length of beam	6	0	
Width of the head in the widest upper part	1	4	}
Ditto of ditto at lowest part	0	9	
Ditto of share behind the wing	0	3½	
Length of surface on which the plough touches the ground	2	10½	
Height from ground to top of beam where coulter goes through	1	8	
Width between stilts at the end	2	6	
Height of ditto from the ground	1	11	
Weight of wood and iron work, about			1¾ cwt.

And it has also a copse rack, or hook with teeth, to admit of more land being given to the plough, or the contrary, which is particularly useful in many cases.

It is noticed, that with a few trifling alterations it is made use of over the whole district, and from that being often called the *Dutch* plough, it is supposed to have been originally brought from Holland by the inventor.

But since its introduction it has received various improvements by different cultivators. In Mr. Bailey's attempts upon it, the mould-board, which is of cast-iron, is so formed, that the sod to be raised presses equally against it, in every part, from the sock point to the place where it leaves it; and it varies from other mould-boards, in not beginning to take its rise from the bottom of the heel, but at least twelve inches farther forward towards the sock, and in being cut away at the bottom opposite the heel, about three inches high, from the sole, by which the turning of the sod or furrow-slice is said to be much facilitated. Thus improved, these ploughs have been found to answer perfectly in different trials, and have been allowed by those who have seen them at work to go with more ease to the teams than those of any other construction.

And it has been supposed that the beam, from its crooked form, which is obvious in some of its improvements, by being fixed so low down in the part next to the handles, makes the plough require less force, and to go in a more sliding manner. And that from the fore end of the beam being so much higher than the hinder part, the holder of the plough has more power, as the draught does not oppose so much resistance to him; for if the beam were fixed to the handles much higher, as is usually the case in other ploughs, this plough would be constantly rippling on the point, and in that way increase the weight of draught. And where it meets with any resistance, such as a stone, it is liable to rise up, while in this form it proceeds in a sliding manner, which affords a steadier motion, and renders it more easily held. Besides, it is much stronger; as in the part where the left handle and the beam are joined, underneath the mortise where the tenor of the beam, by which the bearing of the ploughman on the handles does not in the least affect that part, which in other ploughs is the weakest. In this improvement of the Rotherham plough, the mould-board is so constructed at the breast as to have a slight degree of convexity, instead of being concave, as is often the case,

by

PLOUGH.

by which the furrow-slice is supposed to be prevented from slipping down; and by the keeping the lower part from the ground, when it comes to the turn of the breast, it falls off; consequently, as the furrow-slice has rested on or by the side of the breast, when the plough has advanced twelve inches the work is finished. By this improvement it is supposed that the plough will turn a furrow of any extent, from four to eighteen inches, where requisite, and the same in depth; as the plough that will produce a wide furrow and turn it well, is capable of ploughing deep: the convexity of the breast also causes it to clean itself better, which is a desirable property, as it is thereby rendered less heavy, and less resistance afforded by one portion of earth being prevented from rubbing upon another, and at the same time the work performed in a more perfect manner. The coulter has likewise a position so as to cut in a slanting manner, which causes any resistance to rise up more expeditiously, and the land to be opened with more facility than where it has a more perpendicular direction.

It may be noticed, that where this improved plough is employed with more than two horses abreast, the additional ones must be put before the pair, as it has not land enough to follow single horses.

Thus improved, it has the excellent property of being small and light, while it is sufficiently strong to resist any power that may be applied to it. It is capable of ploughing any sort of land, and in larger proportion than any other except the Norfolk and Suffolk ploughs. The chief improvements which have been effected in the form of this plough, are stated to be in the breast, and in fixing the beam to the handles or stilt. There is also a cock, or a sort of crank, fixed by a screw and nut, so as to keep the share in its proper situation when the plough is drawn backwards.

A representation of an improved plough of this kind may be seen in *Plate XXX. Agriculture, on Swing-ploughs, at fig. 1.*

Wheels have sometimes been added to these ploughs as a sort of improvement for particular purposes; and with either one or two fixed near the points of the beams, without any carriage parts, they have been found to pass through the soil in a very light, easy, and steady manner, and where there are two wheels, to require no holder in many cases, except in setting in turning out of the work at the ends of the ridges. As swing-ploughs, they are probably, however, capable of the most general application.

The *Northumberland* or *Cumberland* plough is an improved plough of this nature, which is held in very high estimation in most of the northern districts, and which performs its work in a very excellent manner, being light, and of little draught. It ought to be much more generally employed than is at present the case on most kinds of soil.

Small's Chain plough is another plough of the swing kind, that is a very useful implement, and capable of very extensive application. It has its name from that of the inventor, who constructed it about forty years ago. It is neatly formed, and very light in its appearance, but at the same time, from the addition of the chain, possessing great strength. It is, therefore, capable of being employed in strong rough sorts of soil, where other sorts of ploughs are liable to be destroyed, as when the share, or even the coulter, in this implement, meets with any sudden impediment or obstructing cause, the stress is immediately thrown upon the chain instead of the beam. The sock is also formed with a fin or feather, by which the firm earth in the bottom of the furrow is cut and moved more readily, and in a more complete manner than could be done by the sock in the common plough. In this plough the mould-board is mostly

made of cast-iron, having a gentle curve, by which the furrow-slice is thrown off with the least possible resistance. It is supposed by Mr. Donaldson to be on the whole one of the best constructed swing-ploughs for all sorts of soils, in a proper state of cultivation, in common use in the island. It is capable of ploughing, with one man and two horses yoked abreast without any driver, more than an acre a day with the greatest ease. An improved plough of this sort is shewn at *fig. 2*, in the same plate on swing-ploughs.

The *Somerville* plough is also an improved plough of the same sort, in which the throat has a more clean sharpened form, and the mould-board is rendered moveable in the manner that will be noticed in speaking of the *Double Furrow* plough. It is capable of being made use of with advantage in breaking up deep stiff soils, as from the moveable nature of the extreme part of the mould-board the furrow-slice can be laid more or less flat, according to the particular circumstances of the case. It is consequently capable of a pretty general use in most sorts of soils.

This sort of improved plough is represented at *fig. 3*, in the same plate on different kinds of swing-ploughs.

The *Suffolk Iron Swing-plough* is another plough of this class, which is found useful in different cases. It was, according to the author of the Agricultural Report of Suffolk, improved by an ingenious blacksmith in that district of the name of Brand, and made wholly of iron. It has been found to answer well in practice, in such lands as are of a strong heavy tenacious quality, and where much obstruction is afforded by the roots and fibres of different sorts of plants and vegetable productions. Its useful properties have been fully experienced in breaking up strong heavy rooty lands on his majesty's farm in the Great Park at Windsor, according to the author of the Agricultural Survey of Berkshire, as it performs its work not only with more facility, but in a better manner than most of those ploughs that are made use of in such descriptions of land. The cops by which it is drawn are said to have been constructed by Mr. Brand, and are extremely well contrived for the purpose.

An improved plough of this description is seen at *fig. 4*, in the plate on swing-ploughs.

Ducket's Skim-coulter plough is another very useful implement of this sort, which is capable of being employed with great advantage where the surface is coarse or grassy, in order to bury it to such a depth as may prevent any inconvenience from its rising to injure the crops that may be sown upon such lands. The principle upon which this plough operates is extremely simple, and of course of a very useful nature, being merely taken from that of trenching ground in the practice of gardening, or that of depositing the surface spit of earth in the bottom of the preceding furrow, and placing the second, or that taken from below, upon it, by which means it is evident that that which was first turned down remains in a state of decay, without any risk being incurred of the grassy material rising so as to produce inconvenience in the operations that may be going on upon the surface. It is capable of performing its work to a considerable depth, where the soils are sufficiently deep for the purpose.

And it has been remarked by lord Somerville, in a little tract on ploughs and oxen, that the skim requires a perpendicular direction, and that the coulter-hole should be removed further from the throat and share, as in the common position it would choke when in work.

By this sort of plough the ground may be opened to any depth in separate horizontal portions of earth; and as the weeds or grassy surface are turned down in the first operation, and covered by fresh earth or mould from beneath,
a larger

a larger proportion of nourishment is supposed to be provided for the crop, while at the same time it is rendered more clean, and the inconvenience of the roots of the grasses or other plants wholly got rid of. It requires a strong team in the heavier sorts of soil, but this is in some degree counterbalanced by the circumstance of one such ploughing being mostly sufficient for the crop. It is consequently evident, considering the number of ploughings generally given in the ordinary way of preparing lands for a crop of barley or turnips, and under the following system for wheat, and the labour and expence in the latter case, in raking, picking, and burning weeds, that the advantages of this plough are probably greater than are generally supposed. It has also advantages in another point of view, which are, that the soil is increased in depth, and the parts of it loosened and broken down, that the fibrous roots of the crops strike and extend themselves more readily in it, and of course are better fed and supported. The noble writer just mentioned thinks, that in thin and sandy soils it is more particularly useful, because it cuts off all which is on the surface, at the depth of an inch, or an inch and a half, in order to its being laid in a state of decay for a future crop, by which an increased depth of soil is given to every subsequent course of crops, and which often acts as a pan or support, to keep up manures in circulation, as their running through such soils too quickly is considered a great misfortune and disadvantage in such soils.

A figure of this valuable implement is given in the plate on *swing-ploughs*, at *fig. 5*.

Besides, it is also capable of being made use of without the skim-coulter as a common plough. When well made, it costs from three to five pounds.

And there is a sort of plough of this nature which has a double share, the one being fixed directly over the other. It is made use of in some of the southern districts with advantage, in putting in one crop immediately after another, as by it a narrow shallow furrow is removed from the surface, and another from below placed upon it, to such depth as may be thought most proper, it being capable of acting to ten inches or more. In this manner many sorts of crops, such as rye and other green crops that have much height of stem, may be turned down without any inconvenience of any of the parts sticking out through the seams of the furrow-slices, by which the farmer has a clean surface of mould for the reception of the grain.

Another plough of this sort, which differs much in the nature of its construction, having a strengthened coultter, and an application of lord Somerville's mould-board made to it, is not unfrequently made use of in some of the southern districts of the kingdom.

This very useful form of skim-coulter plough is indeed much had recourse to in the neighbourhood of Ingatestone, in the county of Essex. And a further variety of this kind of plough is made use of in some parts of Oxfordshire. Mr. Kimber, of Little Tew in that county, both makes and employs this sort of tool, and finds it to be extremely useful for certain purposes. The skim in this implement is fixed to a fore coultter, by which means it is found to do the work much better, than when attached to the common coultter, in which way some have found that it could not work well at all. Upon hollow land, it is, however, not at all approved of, as slicing the surface of such ground is supposed by Mr. Kimber to be much worse than turning it over in the usual manner, and letting the surface-vegetables be laid into the diagonal position, with an edging of them sticking, perhaps, out of the seams. But it is supposed by Mr. A. Young, that in this notion Mr. Kimber is in an

Vol. XXVII.

error; as he contends that the vegetable growth upon the surface is to be rotted in some way, for it is ploughed in in every mode of tillage, and the only question is, how to rot it in such a manner as soonest to convert it into the food of plants, so as they may be able to avail themselves of that food. This surely is the means of lessening, in the greatest degree possible, that additional hollowness which must be caused in a measure, plough it in how you will. The furrow of common ploughing four, five, or six inches, is so shallow, that the warmth of the sun, the moisture of rain, and the influence of the atmospheric air, act to the bottom of it, and will convert vegetable substances into gaseous matter sooner than if exposed to the immediate action of the sun and air, which in all dry weather preserve them, and must occasion a greater hollowness than in the other case, in which they are sooner consumed. And further, the great success which has attended the system counter to that of Mr. Kimber, could not have taken place if his theory was just. Good farmers, when they skim-plough, or common plough hollow land, will adapt the operation to the soil the crop is to be put in, and the season of tillage; and by these means provide a remedy for the expected evil: but this is as clearly applicable to a skim as to no skim at all.

This skim-coulter plough does not answer in some management, or where the soil is of a stony nature, but still many farmers in this district approve of it highly; and some think it excellent, especially for ploughing turnip land for barley, when the weather and treading have made it a little stiff, also, if the fallow for turnips has become a little weedy; but do not use it on layers for wheat, as they plough their lays for that crop deep. Particular farmers, however, find that it makes neat and perfect work on clover lays for wheat crops, not going more than three or four inches deep, and yet skimming off sufficient to bury every thing, and leaving the seams without any vegetable growth to be seen. Shallow ploughing clover land for wheat, is thought essential on these stone-brash soils.

There are still some other modes of constructing these kinds of ploughs, as may be seen in the Essex corrected, and some other Reports of the Board of Agriculture.

There is also a very great difference in the construction of the common swing-ploughs of this district. The *swing-plough* with an improved breast, which is employed by Mr. Weir, is of a very beneficial kind, and is held in much esteem in several different places.

About South-End, in the same county, they have also a *swing-plough*, which is pretty generally in use, but which has an uncommon degree of convexity in the fore-part of the breast.

And a very good *swing-plough*, which has an extremely effective addition for the purpose of keeping the coultter fixed steadily in its place, has been long in use upon all the estates of the late lord Petre.

The *Miner* is an implement of the plough kind, that is very useful for the purpose of loosening the soil to a great depth without bringing it up to the surface, a mode of operation which is particularly useful for various sorts of tap-rooted plants, as well as for extirpating the roots of such weeds as strike deep into the ground. For these purposes it may be employed in the bottom of the furrow after the common plough. It is constructed in a very strong manner, having only a share without any mould-board.

The *Beverston* plough is another sort of useful tool of this kind, which was invented by Mr. Tugwell, and has been employed in some districts in the more heavy kinds of land. It has its principle of draught given it in a very effective manner by an ingenious contrivance of iron work, in which,

PLOUGH.

according to lord Somerville, the point of draught is *perpendicularly* above the *point of action*, or the throat or breast where the share fits on. A plough of this nature is shewn in *Plate XXXI. Agriculture, on Wheel-ploughs, at fig. 1*, in which its dimensions are as follow :

	From	to	Ft.	In.
	1	to 3	6	0
	3	— 4	3	8
	3	— 5	4	3
	5	— 6	2	5
	7	— 6	2	8
	1	— 3	1	5
	1	— 8	2	10
	1	— 9	4	8
Heel to tuck-hole of share			2	6 $\frac{1}{2}$
Tuck-holes to point of share			0	8 $\frac{1}{2}$
	<i>a</i>	— <i>b</i>	2	4
	<i>d</i>	— <i>e</i>	2	5
	<i>c</i>	— <i>d</i>	1	4
	<i>d</i>	— <i>e</i>	2	5
Diameter of wheel			1	9
	<i>d</i>	— <i>f</i>	0	11
	<i>g</i>	— <i>b</i>	0	10 $\frac{1}{2}$
	<i>e</i>	— <i>i</i>	1	0 $\frac{1}{4}$
	<i>k</i>	— <i>l</i>	0	9
Breadth at heel			0	9
Breadth of fin			0	7
Top of beam at heel to ground			0	8 $\frac{1}{2}$
Mould-board projects at top more than breadth at heel			0	6

The *Double Furrow* plough is a kind of implement of this sort, which has, at least in its improved form, been found highly useful and advantageous. Ploughs of this sort have been constructed in various ways, as with a double beam, and with a single beam only, which is the manner in which they are usually made at present. But the most improved plough of this nature is that constructed by lord Somerville, and for which he has taken out a patent. It is advantageous in performing more labour in a given time with a certain strength of team, than other sorts of ploughs, as producing two furrows at a time. It has been found useful on the lighter sorts of land where the ridges are straight and wide, though some think it more confined in its work than those of the single kind. A principal advantage in which it excels other sorts of ploughs, is in the saving of the labour of one person, and in doing nearly double the work with but little more strength in the team, in the same time. It is remarked by his lordship, in speaking of this sort of plough, in the second volume of *Communications to the Board of Agriculture*, that the clean and sharpened construction of the breast and throat will warrant their breaking deep stiff land with infinite success; in this case the coulter should be set nearly straight with the throat and shares: in cross ploughing, or stirring, they may be set three-quarters of an inch towards the land, by which greater dispatch will be obtained in seed time. Should they carry too deep a furrow, the correction of their shares is obvious; should they hug too much to the land, or go unsteady to the ploughman, it must absolutely proceed from a want of setting them true, relatively to each other, and from an undue regulation of the cops; here a nice attention is required: their power also of cutting a furrow level at the bottom should afterwards be proved on a level floor. The want of this practice in the matter has condemned many a good plough, when the fault was in the ploughman only. It may suggest itself, that two-furrow ploughs are unfit for

hilly ground, but the very reverse is the case. The effect of ploughing across the inclined plane, or hill, is that of carrying the soil in time to the bottom of the field, which must be carted bodily up again at a great expence: let such land be worked from the top to the bottom; let one furrow be carried with the hindmole or land share up the hill, and two-down, so will the power be apportionate to the weight with which it has to contend, and needless toil to the team will be saved. That power which was required to carry two furrows up would be superfluous in carrying the same down the hill, and the effect will be as 3 to 4, that is, an acre and a half, instead of two acres *per day*.

A plough of this improved construction may be seen in the plates on *wing-ploughs, at fig. 6*.

In regard to the improvement of these ploughs, his lordship observes, in his tract just noticed, that from the design, which represents a side view, it may be observed that, besides the moveable plates, there are coulter, itays, &c. and how firmly the plough is put together, and how little waste there is of timber and iron work. And after noticing its construction in the breast so as to lessen resistance, it is added, that the double-edged coulter is formed also to produce this effect; in strength and substance it is equal to the common or narrow coulter, and being less broad, presents so much less for resistance: when in work, the itay gives a steadiness to it, the coulter being subject to frequent derangement, to correct which must occasion frequent stops, alteration of the wedges, and loss of time. And it is afterwards stated, that an economical and spirited system of farming labour already prevails in some districts; in none more eminently, with respect to ploughing, than in Essex, on both banks of the Tweed, in Suffolk, Yorkshire, and Norfolk. Here it would be no object to invade the system already established, for innovation is not palatable to farmers; nor should the first deep ploughing in Kent give way to any novel system; there can be no better husbandry: but, except for beans and tap-rooted plants, subsequent deep ploughings are injurious, both as to expence and effect. Dr. Hunter, in his *Essay on the Roots of Wheat*, points out the depth needful for the supply of seminal roots in wheat and wheat corn in general; that which is turned down then, in the first deep ploughing, should be rotting for the succeeding crop. Let not the bottom know what the surface is doing! Here two-furrow ploughs, even admitting them incapable of carrying a deep furrow, which is far from true, must come into admirable effect, for a twofold advantage can be taken,—of the season in sowing, and the work being done at half the expence. But where men are chained down by long usage, and perhaps, for the convenience of constant road work, to teams of heavy corn-eating cart-horses, two-furrow ploughs become, he supposes, objects of extreme importance, because their horses will not feel the difference between their own single furrow, working one acre, and the well constructed two-furrow plough, with two acres *per day*: here is no system deranged, and double work done.

The counties of Leicester and Stafford have profited much by their use under these circumstances, although their two-furrow ploughs, in other respects good, have never been so constructed in the throat and breast as to destroy the means of resistance. Without doubt, obtusity in these particulars must add incalculably to the weight, must break the furrow, and so spoil the work; moreover, let it not be forgotten, that removing resistance not only diminishes the labor of the cattle, but is also of equal advantage in increasing the strength of the implement;—the resistances with a well constructed, and with an ill constructed plough, in performing the same work, are as different as the resistance

PLOUGH.

of a well constructed king's cutter, and of a floundering Dutch merchantman, failing with equal velocity.

And the noble inventor adds, that in his own county these ploughs have met with a reception more favourable than could be expected in so short a period. On the 16th of October, 1798, two-furrow ploughs were not thought capable of breaking up ley-ground, although in constant use for fallowing, but from their construction requiring six oxen. On the 16th of October, 1799, a very large and respectable farming society gave a premium for two-furrow ploughs, working ley-ground only. On the day following, in the presence of many members of this society, one acre and a half of ley-ground was broken up by four oxen, with infinite ease to themselves, in three hours and fifty-five minutes, they having, as part of a constant course of work, ploughed seventeen perches short of an acre of ley-ground the same morning: this was done to prove the effect of moveable plates at the extremities of the mould-board, that the furrows might be laid more or less flat; for mould-boards, formed to lay furrows in ley, so as to give the moist soil to harrows, cannot be of that form best calculated to make good work in stirring earths, more especially the last, which ought to be thrown up in small seams, as it were, that the seed may be duly buried. It has hitherto been held necessary to rip off the plate for this purpose, and drive in wedges, by which the mould-plate must be injured. From the trouble attending this operation, it has for ever been omitted, and the land, of course, imperfectly worked. But this inconvenience may be remedied, and the mould-board be adjusted with great facility and expedition, by the following means: when the mould-board is formed, and its plate fitted as usual, let the parts marked *a, a*, be cut off, and again connected with the fixed part of the mould-board by means of flat hinges, or of thin flexible plates of tempered steel, or of hard hammered iron, so as to admit of those parts being set to have different inclinations with the fixed part of the mould-board: by means of two screws passing from the inside through the lower parts of the handle of the plough, opposite the backs of these moveable pieces *a, a*; those screws may be made to keep them at any desired degree of inclination, according to the nature of the work to be performed. It is stated farther, that ley-grounds cannot be laid too flat, or seed-earths too much on an edge; and by this improvement of the mould-board the plough may be instantly adjusted for either purpose: when these moveable parts are screwed outwards, it will cause a proportionate convexity in the base of the furrow, and so give more earth to cover the seed. That plough which can give most mould to the harrow is the best for a ley crop. That part of the mould-plate that is marked with the dotted line *cc* being found most liable to wear, should be made of a double thickness, that is, twice the thickness of a new crown-piece; it will then last nearly as long as the plough. The increased weight of draught, when these moveable plates were extended, did not appear, in a two-furrowed plough, to be by the cops more than twelve pounds, in ley-ground, at six inches depth. It is needless to state the success of these alterations; and the friction in furrows required to be laid flat was less than could be supposed, probably not more in both furrows than from twelve to six pounds.

With regard to the moveable mould-plate, and its operation on the furrow. If the breast of a plough be obtuse, the whole struggle lies there,—there is the furrow turned, and the hindermost part of the mould-plate has little or nothing to do: the furrow may be well laid for one particular sort of work, but the breast of the common plate can only be of one form, therefore can only turn one description

of furrow; and this must be done at an increased weight of draught: this is beyond all contradiction. In these moveable plates, the furrow is not turned until it reaches the remotest point of action, at a distance of two feet from the point where the furrow is cut off from the land. By the gentle and progressive turn of the mould-plate, the earth hangs balancing, as it were, in the air, and the slightest pressure of the moveable plate lays it over. The principle of this plate is, as has been seen, to deposit the furrow at any angle required, and to qualify it thereby for the different purposes of husbandry. There is another principle in ploughing equally well established; namely, that the base or bottom of the furrow must be cut level and true, or the surface of the work will be untrue, and the crop derive otherwise material injury. To effect this, the plough must go close at heel, and upright in its work, therefore the furrow must assume one form only. A third principle equally certain is, that in ploughing ley-ground, or for sowing on one earth, the furrow should be laid far more flat than is advisable in the last stirring or seed earth. As for barley, &c. hitherto, we have obtained one of these objects at the expense of the other. No two-furrow plough could, for an instant, make work, except in an upright direction; for if it did, the land or left share would be buried too deep, and the furrow, or right share, would be thrown out of work. But still further the writer will be bold to say, that no single-furrow plough, whether constructed in China, in France, or in England, has ever yet, or ever will be able to answer all these purposes, without the aid of a moveable plate; and therefore, however good for a limited purpose it may be, it cannot be called a perfect implement; it is incapable of doing all that is for ever required of it to do. It would be the height of folly and extravagance to construct two implements where one would do. He therefore sits contentedly in the conviction, that these plates must be resorted to. And in many cases, the moveable plate will probably supersede the use of the turn-wrist plough.

His lordship adds, that it cannot be deemed irrelevant to the subject, here to state the result of a challenge given to the owner of these ploughs, to plough 24 days work successively, on his majesty's farm, either at Kew or Windsor, on the 10th of March. The challenge was accepted, and it is a matter of regret that this challenger did not venture to appear, although repeatedly urged to do so: because a trial for such a length of time, and between two breeds of cattle so distinguished for their powers in labour, must, his lordship supposes, have thrown great light on a subject of such importance to the farming world. That something, however little, might be proved, his majesty was pleased to allot the only piece of land then unfurrowed, 17½ acres, statute measure, which was ploughed by a two-furrow plough, four Devonshire oxen, six years old, a man and a boy driver, in six days and a few hours: the oxen were in good order at the commencement of their work, and finished it in higher order, as well as in flesh, than when they began. This is a strong fact; but numbers in the vicinity of London know it, and are ready to prove the fact. These oxen, as is the custom in their county, never tasted corn.

Mr. Perrott of Evesham, speaks of these ploughs as doing their work well, and as being on the best construction he ever saw. And Mr. Weitphaling of Radvale, near Rofs, in Herefordshire, observes, that this plough certainly makes exceeding good work, and turns the furrows remarkably well. The time of its arrival was not the most favourable, as their soil, in general light and easy, is now, by the wet and fun, caked, and works with great difficulty; notwithstanding which, not one farmer but says it will be of great

PLOUGH.

ute in many instances. It is lucky for him that his ploughman likes it double, and is inclined to use it on all occasions. Mr. Dougall also observes, that Mr. Shirely from Warwickshire gives a good account of the double-plough; and sees no difference between the draught of four horses in the double, and his own single-furrow plough; a circumstance which has been noticed by others in some cases.

With regard to the advantage of these ploughs, his lordship offers the testimony of another person, personally a stranger to him; his partiality, therefore, is to the plough itself; not to the inventor. He is not disposed to draw absolute conclusions from ploughing-matches, because much may depend on accident; besides that, exertions might be made for three hours, without much apparent distress, which nevertheless could not be maintained for three weeks, and so the public become misled. Yet, as this match was much talked of, and many questions on the subject put to him, he wrote to Mr. Tweed to know the particulars: his tale is plain and unvarnished.

Mr. Tweed's land is strong and stiff in quality, and not a turnip has been sown there for more than twenty years past: it is what we term bean and wheat land. The practice of that country has been to allot 100 acres of land in tith to four horses; therefore let it be remembered, that the saving of expence obtained by the use of the two-furrow plough does not arise from a comparison on lands, expensively cultivated with four or five horses, incurring a charge of twelve, sixteen, or twenty shillings *per acre*; but in the county of Essex, and in the vicinity of Chelmsford, where it has long been a system to work these strong soils with two horses and no driver: and where this art is allowed to be as well understood, and practised with as much skill and economy as in any part of Europe, Flanders not excepted. Mr. Tweed's account of the business in a letter to his lordship, is this: "In answer to the letter I have just had the honour to receive, I take the liberty of stating the experiments I have made with your two-furrow plough upon strong land, as well as the result of the only match I have yet been engaged in. I put my first plough to work with three horses and one man, against two of my own, and four horses, held by two remarkable good ploughmen, who are very much averse to any new implements: after exerting themselves to the utmost every day for a month, upon clover lays, bean and pea etches, for wheat, they allowed, very much against their inclinations, that it performed the work best, which is entirely owing to the superior form of the breast, and the great advantage derived from the moveable plates. This trial having perfectly convinced me that there is an absolute saving of five shillings a day every day they are used, I ordered a second, and soon after a third, and have ever since had all my work done with them, nine horses, and three men, which before employed six ploughs, twelve horses, and six men, causing a reduction of one-fourth the horses, and one-third of the men, and is, in my opinion, one of the greatest improvements that ever was made in agriculture, for which I conceive the public and myself highly indebted to your lordship. Being at Mr. Lovibond's rent dinner (the gentleman I live under), I made a proposal to the company, who were all farmers, to plough, for a wager, two acres of any land with the two-furrow plough and three horses, as well, and in the same time, as one acre could be ploughed by a single one and two horses. This was accepted by Mr. Gibling of Hatfield, and a field of his fixed upon that had been sown with rye directly after harvest, (stubble) upon a wheat etch, and being fed by bullocks and sheep in wet weather, poached a great deal; and when the ploughing took place, was extremely dry and bound. A great num-

ber of spectators attended; at starting, the odds were three and four to one against the two-furrow plough, as it was supposed not able to break up and turn hard work; after a fair contest, five farmers were appointed umpires, who were unanimous in their decision, that the two-furrow plough, having executed the work soundest and best, and in the least time, was entitled to the wager.

Sandon, 1802.

I remain, &c.

"In a second trial, the sweepstakes were adjudged by the umpires to the double-furrowed plough of Mr. Thomas Little Tweed, of Sandon. A double-furrowed plough was allowed, by the articles, to have four horses; but Mr. Tweed's was worked with only three, and ploughed two roods, not only in the best agricultural manner, but within considerably shorter time than the other common plough did their one rood." The noble writer adds, that in addition to this testimony he has only to say, that it has not been his ill-fortune to verify the old adage, which says, "a prophet is no prophet at home;" for these ploughs are spreading, with unexampled rapidity, over the county in which they originated: and at a very large meeting of farmers, held there lately, no ploughs of any other description appeared, and the prize given by subscription was contended for by these ploughs only.

It has been argued, that a two-furrow plough, with the double mortised beam, has an advantage over that of the curved single beam, inasmuch as, by a screw, the beams can be brought nearer, or set more apart, for the purpose of cutting a wider or narrower furrow. In common ploughing, no great benefit was contended to result from this power, but in sowing under furrow, great things were to be expected. Now let us look round, and see where the tillage husbandry is reputed to be good, and single-furrow ploughs in use, consequently, the size of the furrow is optional; let us see whether the wide or the narrow furrow is preferred. We can in a moment instance the usage of the country round Weltham, in Essex, and Peterham in Moulsey, in Surrey. In both instances the land is level and good, and the broadcast husbandry very high in reputation, as their crops, on an average of years, are ready to testify. Here the seed is ploughed in at a ten or sometimes at an eleven inch furrow. We are not, however, to establish a general system on two or three instances—twenty or thirty might, perhaps, be adduced; but they are worth, at least, one assertion. It has been his determination to avoid, as much as possible, any comparison of other implements with his own; but he may say, that he learns from one, who is as good a judge of husbandry as any among us, and has compared the double-beam two-furrow with that of the curved single beam in mortising and iron-work, and consequent tendency to derangement, there is an absolute difference of one horse in four in favour of the patent plough.

And if land is inclined to be wet and stiff, the less trod it is, the better. Here Mr. Tweed's mode is to work three horses, one on the land, and two in the furrow, one before the other, instead of three abreast; and it appeared by the regulation of the *cops*, that is, an iron screw, acting through the end of the beam to regulate the depth of work, how little he has added to the weight of draught. It is almost needless to say, that the true point of draught should be exactly in the centre notch of the *cops*; any deviation to the right or left can only be for the purpose of counteracting a false friction or pressure, which must have added to the weight. The size of a furrow, provided it be of just proportions, is optional; that which he has preferred is nine inches and a quarter, and for every purpose of husbandry he knows of none better. It will give as much

PLOUGH.

mould, or 'crumb,' (as we term it, provincially) to the harrow, as any other furrow whatever: this is the best object in ploughing for a ley crop. If ley peas are to be sown, every other furrow, at nine inches and a quarter each, there will be an interval of eighteen inches and a half between the rows; a distance as much approved of as any we know. At every third furrow for beans, the interval will be twenty-seven inches three quarters; at every fourth furrow, thirty-seven inches; and it must be allowed, that if any implement be attached to a plough for the delivery of pulse, or white grain in drills, the upright position necessarily belonging to the two-furrow plough, when in work, will qualify it admirably for the purpose.

Upon the whole, these observations place the utility of double ploughs in a point of view, that seems to deserve the notice of the practical farmer in a much greater degree than has hitherto been any where done.

Norfolk Plough.—This is a kind of plough, that is held in much esteem in that, as well as some other light districts, as performing the work in an easy and expeditious manner without any great strength of draught. The carriage and wheels in all ploughs of this nature, however, form objections to them, and at the same time render them awkward, clumsy implements. An improved plough of this sort is shewn in the plate on wheel-ploughs, at *fig. 3.*

The head and beam are short; while the carriage part and wheels stand very high in this sort of ploughs, of course the fore end of the beam is much elevated, by which, advantage is gained in driving the horses or team, as it is usually drawn by two horses yoked abreast, the ploughman directing them by reins, by which there is a saving of one person in the business.

In the county of Essex, Mr. Rogers prefers the Norfolk plough, in two circumstances, to the common wheel-plough of that district: the point of the share is nearer to the points in the wheels, where they touch the earth, a shortness which, in his opinion, eases the draught; and the mould-iron or plate, as it is called in Norfolk, turns the furrow better.

The common Essex *wheel-plough* is said, however, to be a very good tool of this sort, and which is used extensively all around the town of Kelvedon. It has the carriage part for the wheels somewhat in the form, and the beam raised up at the point much in a similar manner to that in the Norfolk plough.

Kentish Turn-wrist Plough.—This is another sort of strong plough, much used in the strong heavy, flinty or rocky soils in that district. It is a very powerful implement in such sorts of land, but extremely clumsy, heavy, and awkward. The expence of it, when complete, is mostly about five or six guineas. A representation of it is given in the plates on wheel-ploughs, at *fig. 4.*

In the survey of that county, it is described as consisting of a beam of oak ten feet long, five inches deep, and four broad, behind which is a foot five inches by three and a half, and three feet and a half long, on the top of which the handles are placed; the foot is tenoned to the end of the beam, and mortised at the bottom to the end of the chep. Through the beam, at two feet five inches distance from the foot, is a sheath of oak seven inches wide, and one and a half thick, which is mortised into the chep in an oblique direction, so that the point of the share is twenty-two inches distant from the beam. The chep to which the share is fixed is five feet long, four inches wide, and five inches deep. The share is of hammered iron, weighs about thirty-two pounds, is twenty inches long, and from four inches and a half to seven inches wide at the point. The upper

end of the beam rests on a carriage with two wheels, three feet two inches high. On the axle-tree is a gallows, on which is a sliding bolster to let up and down. Through the centre of the axle is a clasp iron, to which is fixed a strong chain called a tow, that comes over the beam, so fixed, as by means of notches (or a pin called a check) to let the whole plough out a greater length from the axle, thereby letting it down to a greater depth.

A different kind of *turn-wrist* or *revolving* plough has been lately invented by Mr. Lumbert, in which there are two shares, one of which at the end of each furrow, or every length of the field, turns round, and lays another flag by the side of the last, disposing it all the same way, in a somewhat similar manner to that which has been described above. Figures of this implement may be seen in the Corrected Report of Oxfordshire.

And besides these different sorts of ploughs, there are various other kinds in use in different districts, as the *Single* and *Two-wheel Plough*, both of which are good ploughs for particular purposes; but any of the light swing-ploughs, may be readily converted into wheel-ploughs simply by the addition of that apparatus.

Also the *Hampshire Patent Iron Plough* is a very useful plough in some cases. It is seen at *fig. 2.* in the plate on wheel-ploughs.

A plough has likewise lately been invented, in Berkshire, by Mr. Berriman of Speen, which is denominated a *Pressing Plough*, and which is held in much esteem by many persons, who have given it a sufficient trial, especially upon clover lays. It is constructed under a patent, and costs about twelve guineas. It is stated by the inventor and patentee, that it "is intended to be drawn over the land recently ploughed, in order to press in the grips or channels made by the common ploughs, that no hollow places may remain for the seed to be buried too deep, and that every kind of grass, stubble, or any thing else, may be pressed into the ground. After the field has been pressed, almost any kind of seed may be sown by broad-cast; and it will, by rolling into the channels of the pressing wheels, be evenly and equally buried at a proper depth, after being harrowed, and consequently be kept out of the way of birds, and will come up more regularly. It is evident, therefore, that there is no necessity for sowing so much seed to an acre, as in the common broad-cast husbandry; thus combining the advantages of the drill and the broad-cast systems. This machine is also of such a construction, that in the most uneven ground, every wheel acts as fully and amply as if it were drawn over a level surface. One of the pressing wheels, with or without the line before it, may be put before a common hand drill, and drawn by one horse, by which means any ground, however foul, may be drilled; or a drill may be added to the pressing machine, which has been described, with three wheels, so as to throw the corn into the channels."

Tools of the plough kind have likewise been contrived with more than one coulter, in order to reduce the surface more effectually; but these have in modern practice given way to implements of the harrow kind, such as cultivators, scarifiers, scuffers, &c.

Double Mould-boarded Plough.—This is a kind of plough often used with advantage in making the furrows in setting potatoes, cabbage, and other similar crops, and earthing up such as are planted in wide rows. Those whose mould-boards move on hinges, and may be set wider or narrower at pleasure, are the most convenient.

Single-Hoe Plough.—This is also often useful in stirring the mould in the intervals of different sorts of crops, and laying

laying it to the roots of the plants, and thereby preventing the growth of weeds. The mould-board in this plough is so constructed, that it can be raised or depressed at pleasure according to the nature of the crop, and the intention with which it is used.

The *Single-Horse Plough*, too, is extremely useful for several purposes in tillage husbandry. This sort of tool is very common on the farms in the county of Norfolk, but they are made upon a very different and much inferior construction to this, which is in use upon the estate of Mr. Western in Essex, and found to work extremely well, but without a wheel. The different parts have the following proportions in his ploughs of this kind.

	Feet.	Inches.
From 1 to 2	6	2
1 — 3	2	6
5 — 4	3	2
2 — 6	1	1
3 — 13	0	6
13 — 4	1	4
8 — 9	1	10
8 — 14	1	2
4 — 12	0	11
15 — 16	0	9
a — b	1	0
c — d	0	6

Ploughs have likewise been invented and constructed entirely without coulter: of this kind is the *Argylshire* plough, contrived by the Rev. A. Campbell, on which it is observed, that as the common plough is very liable to be choaked by an accumulation of stubble, &c. in the narrow angle under the beam before the coulter, and, not unfrequently, is thrown out of the ground, by catching small stones or shells between the points of the coulter and sock, both these inconveniencies have therefore been attempted to be obviated by throwing aside the coulter altogether, and supplying its place by an upright feather attached to the *land* side of the sock, and which serves the purpose of slicing off the furrow in the same manner as a coulter; for, being laid off on the same angle, it is found, in practice, to succeed to admiration. Small ploughs of this sort employed in horse-hoeing turnips, beans, cabbages, &c. of which the weight of the wooden part is about forty pounds, and of the iron-work about thirty-six, and cost about two pounds ten shillings each, are made in a very accurate manner, by Messrs. Brown and Co., coach-makers, Abbeyhill, Edinburgh, who have made several, and can supply any number of them on demand. This plough is found to answer extremely well, more especially in taking the earth away from the sides of a drill crop; for which purpose it is conceived to have attained absolute perfection; as its broad upright feather, which operates as a coulter, completely shields the plants from all risk of earth falling on them from the left side of the plough, while, at the same time, the ploughman correctly ascertains, that the part of the plough below ground, approaches no nearer to the roots of the plants, than the upper part does to their leaves; so that he can bring the plough to slice off the earth close in upon their sides, where necessary.

In point of draught, it is precisely the same as the common plough. It obtained the premium from the Highland Society.

And the same gentleman has invented a very curious and useful muzzle or cope for ploughs, which, by a single twist of a screw, gives both *earth* and *land* or depth and breadth at the same time, or either, as may be requisite, even in the

most minute degree. It weighs from ten to thirteen pound according to the size of the plough it may be used for, and costs from nine to thirteen shillings. It is strong and durable, and may be had at the above manufactory.

There are still a few other kinds of ploughs, which are contrived and constructed for the purpose of accomplishing different views and intentions in husbandry, such as those for paring or taking off the surface or sward of the land, in different circumstances; for the removing of the wetness with which it may be impregnated or saturated in its more superficial parts, and for the forming and improving of roads in different cases, &c., as may be seen under their several proper heads.

In the first of these intentions, the *common paring plough*, and the *improved paring plough*, which is in use in the county of Chester, are extremely good tools, especially the latter, which is very much employed in different parts. See *PARING and Burning*, and *PARING-Plough*.

In the second view, there are different sorts of ploughs made use of in different places, and according to the different circumstances and soils in which they may be employed. The *common draining plough* is had recourse to in some of the midland districts of the kingdom for the more general purposes with great success, for which it is said to be a good, and not very expensive tool. The *drain* or *gutter* plough, which has been recommended by the duke of Bridgewater, is also an useful plough of this kind. It has been found beneficial in forming at once gutter drains on grass lands, which are retentive of moisture, but it requires a great strength of draught in all cases. The *common mole plough*, and the *improved mole ploughs*, by Lumbert and others, are likewise very good implements in many cases especially those of the latter kinds. There are also some others, which answer different purposes of the draining kind in a very effectual manner. See *MOLE-Plough*.

In the last intention, a very useful plough has been invented by a blacksmith of the name of Brand, which will be described under the head of roads. See *ROAD*.

PLOUGH, among *Book-binders*, is a tool with which they cut the leaves of books smooth. See *BOOK-BINDING*.

PLOUGH, or *Plow*, in *Navigation*, an ancient mathematical instrument made of box or pear-tree, and used to take the height of the sun, or stars, in order to find the latitude.

It admits of the degrees to be very large, and has been much esteemed by many artists; though now generally disused amongst us.

PLOUGH-Alms, a duty anciently of a penny, paid to the church for every plough-land, or hide of land.

“De qualibet carucata juncta inter Pascha & Pentecosten unum denarium, qui dicitur plou-almes.” *Monast. Ang.*

PLOUGH-Bote, in our *Old Writers*, a right of tenants to take wood to repair ploughs, carts, and harrows, and for making rakes, forks, &c.

PLOUGH, Gallows of a. See *GALLOWES*.

PLOUGH, Handles of a, the name given by farmers to the two pieces of the plough fastened to the earth-board, and to the sheat, and serving the ploughman to rest his force upon in the guiding of the plough. When they are considerably long, the plough is always guided the better, and the land is better tilled; but the lazy ploughmen are apt to cut them off shorter, that by bearing their whole weight upon them, they may, in a manner, ride, instead of walking. If they should ride, in this manner, on the long handles, they would tilt up the end of the beam, and raise the plough out of the ground.

PLOUGH-Head, a name given by the farmers to the foremost

moist half of the plough, or that part containing the two wheels and their spindle, the box, the crow-staves, the pillow, the wilds, the tow-chain, and bridle-chain, and the stake. See PLOUGH.

PLOUGH-Land, carucata terra, in our *Ancient Customs*. See CARRUCATE.

PLOUGH-Monday, the next Monday after Twelfth-day. The ploughmen, in the north-country, on this day, draw a plough from door to door, and beg plough money for drink.

PLOUGH-Tail, a name given by the farmers to that part of a plough which contains the beam, the coulter, or coulters, the share, the sheat and under-sheat, the earth-board and handles, as also the drock, the ground-wrinks, and the retches. See PLOUGH.

PLOUGH-Jogger, a term provincially applied to a ploughman of the more ordinary kind: a sort of bungler in the work of ploughing.

PLOUGH-Wright, a term applied to a person whose business it is to make ploughs, and other implements of husbandry. Workmen of this sort are mostly very common in all country situations.

PLOUGHING, the act of breaking up, and loosening the soil by means of a plough and proper teams. This or some other mode of loosening and turning up the upper parts of soils, is in all cases necessary to render them more suitable for the reception of the seed and the growth of the crops, and they have been constantly in practice since the very infancy of the art. As it is only by some such method that a proper bed for the roots of the young plants can be prepared, and a proper condition of the land for supplying them with nourishment be provided; in performing the operation it is a matter of great utility for the farmer to have particular attention not only to the state and nature of the ground, but also the season of the year, and kind of crop that is to be cultivated, as in this way the preparation of his lands may be rendered more perfect and suitable, and at the same time some of the natural defects under which they labour be removed. In almost every sort of soil it has been observed, that ploughing them up before the latter end of the autumnal or beginning of the spring season commences, renders them capable of imbibing and retaining a large portion of moisture for the succeeding summer; while the turning them up during the spring and summer, causes much waste and discharge of moisture by evaporation and other means.

In cases where the soil in its natural state is too dry, and possesses too little tenacity for the growth and support of such crops as are necessary to be put into the earth in the spring months, the land, by being fully brought into a state of preparation for the crop in the autumn, and the seed introduced without any additional ploughing in the spring season, may be preserved in a more moist and adhesive condition, consequently in a more proper state for the growth of such crops; but where the soil is naturally moist, and the crops that are to be cultivated require that it should be dry and mellow, when they are put into the ground, the ploughing, by being deferred for the winter, and performed as late as possible in the spring months, when it is become a good deal dried, will be the more advantageous for the crops that are to be grown upon it. But there are other circumstances that constantly demand attention in the process of ploughing land. In all the stiff, heavy, and more adhesive kinds of soils, that are much disposed to the retention of moisture, whether they be perfectly clayey or have more of a loamy quality, it should be a common rule never to plough or turn them up when wet in any degree, except where the nature

of the crop requires it: as when such sorts of lands are ploughed under such a condition, the parts of which they are composed are very apt to cake and run together into hard lumps, that require much trouble and difficulty to be afterwards reduced into a fine state. And further, great injury is produced by the treading of the team, as well as a much greater power necessary in performing the operation. They should not, however, be suffered to become in such a state of dryness as to oppose too much resistance before the work is undertaken. It, however, has been suggested, that in all such lands where the clayey material is the most predominant, the ploughing may be performed when the ground is wet without injury, where the work is executed before the commencement of the frosts in the winter, while in the spring the team should not be suffered upon the ground until it be in a properly dry condition. Communications to the Board, vol. iii.

But in all those sorts of land where there is a considerable depth of vegetable earthy matter, as those of the moss, moor, peat, and fen kinds, the ploughing of them, when under the state of tillage, should be executed when they are in a favourable condition in respect of dryness, as under the contrary circumstances they can rarely be ploughed with benefit, and in many cases not at all.

However, in most of the more light dry sandy or gravelly sorts of land, and perhaps in some of the more mellow descriptions of the loamy kinds, the work of ploughing may be had recourse to, especially in putting in the crops, when they are in a considerable degree impregnated with moisture, without any disadvantage being sustained, and sometimes even with benefit, as they are liable to part with their moisture in too quick a manner. This circumstance should indeed direct the farmer in such sandy sorts of land, to stir them as little as possible when the season is hot and dry, so as merely to keep down the weeds, as much mischief may otherwise be done by the exhalation of moisture that may be caused. These sorts of lands are of course managed with much less trouble and expence of teams, as well as with less difficulty in respect to the state of the weather, than most other sorts.

The depth to which lands should be ploughed, should in some degree vary according to the nature of the soil, and the crops that are to be grown. It would likewise seem proper that the feed furrows should have less depth than those ploughings that may have preceded it; and perhaps, in general, deep ploughing is not so necessary as has been supposed, except in the cases of tap-rooted plants. It has, indeed, been well remarked by Mr. Kent, in his Hints to Gentlemen and Farmers, that though deep ploughing has been much advised by different writers lately, on such sorts of land where the bottom and surface are of opposite qualities, and neither of them good; a mixture may in such cases be advantageous, and may be effected by their going below the usual depth; but where the top and bottom, to the extent of eighteen or twenty inches, are similar, he does not think it ever proper to exchange the surface part, which has been gradually for a great length of time increasing in fertility, for the under part, which has only the property of being more fresh. He has stated that ploughing deep, except for certain sorts of crops as above, is never requisite or adviseable. The growth of the common crops of corn or of grass does not require any great depth. He likewise remarks, that where ground is ploughed to a great depth, the roots of weeds are only turned over, without being removed or thrown upon the surface to decay, while clean light or shallow ploughing dislodges them in a perfect and effectual manner. In some districts, as that of Cornwall, where

PLOUGHING.

where the soil is extremely shallow, a large produce is afforded; and in several other counties the land is found to be injured by deep ploughing, or going below the usual depth, to which the lands have been ploughed. It is added, that hand-hoeing is known to every one to be more effectual in cleaning land than a ploughing; and the process of paring and burning renders land perfectly clean, though it be only two inches in depth. All these tend to shew that ploughing to a great depth is by no means necessary in the cleaning of land; and it cannot but be generally admitted, that the longer the manure is kept within three or four inches of the surface the better, especially on light soils, through which it is apt to sink and escape too quickly.

It is, however, stated in the Calendar of Husbandry, that in some of our well cultivated counties, the shallowness of the ploughing is remarkable; when almost every other point of management is very spirited and complete, a deficiency in this may not be at once perceived in the crops; but no doubt failures are often caused by it, though attributed to other circumstances. Therefore the following hints are thrown out: 1. An additional depth should first be gained in autumn, that a successive change of seasons may take effect in atmospheric influences before any seed is ventured in the raw stratum brought up. 2. The quality of that stratum should be examined; it is sometimes sterile by reason of an acid, discoverable by boiling in water, and putting that water to the test of blue infusions. 3. Animal and vegetable manures cannot be buried: at whatever depth they are deposited, their constant tendency is to rise to the atmosphere. 4. Fossile manures are extremely liable to be buried, having a constant tendency downwards. Chalk marle and clay are sufficiently soluble, or so miscible with water, as to sink in a regular mass; and are sometimes found much below the path of the plough. 5. In soils of a poor hungry quality, there should be some proportion observed between the depth of ploughing and the quantity of manure usually spread; but this does not hold good on better soils. 6. Soils are rarely found that ought not to be ploughed, in common, six inches deep; many ought to be stirred eight inches, and some ten. 7. One deep ploughing (to the full depth) should, it is conceived, be given once in twelve, eighteen, or twenty-four months; if this be secured, shallow tillage by scaling, scarifying, scuffling, skimming, or broad-sharing, is in many cases preferable to deep working oftener, and especially for wheat, which loves a firm bottom.

But with regard to the depth of breaking up grass-land, it should be considered according to the manner of performing the business, as by the process of paring and burning, and by that of merely ploughing. In regard to the first, it is nearly a general opinion in almost every part of the kingdom, that the first ploughing after the operation should be shallow. It cannot, however, be admitted, that though the notion be far spread, it is therefore just, as the same thing prevails every where with respect to dung and the sheep-fold; in which cases there is great reason to think it erroneous. Manures that purify, and of course become volatile, cannot be buried, as have been seen above: plough as deep as you please, they all rise sooner or later into the atmosphere; but with fossile bodies, and probably with the ashes of paring and burning, the case may in a great measure be different, and the good success of the usual management affords reason to justify the principle on which it proceeds. It may, therefore, be deemed a safe maxim not to plough after this operation for the first time, more than three, or at most four inches in depth. In the other mode of breaking up grass-land after much experience, the writer has not found much difference either in the produce or effects on gravelly,

clayey, or sandy loams when executed in either way. In districts where they usually plough as deep as six or eight inches, he has observed (and it has been his own practice) that they plough up old grass-land shallower, that is not above four inches deep, or at most five; the crop being every where put in upon this earth, except in the case of summer-fallowing peaty or moory lands. By not ploughing deep, the atmosphere has a more direct influence in assisting the putrefaction of the sod covered, as it is with the crop which is probably one of the smothering kind.

But that two circumstances are here to be attended to, which are the use of the skim-coulter plough, and that of sowing on a stale furrow.

This plough he considers as one of the most effectual and applicable implements for breaking up this sort of land. It is well known that when this is done by a common plough, there is a seam between every furrow-slice of grass and weeds that grow through the summer to the injury of the crop; but which is wholly prevented by this plough, which is applicable in all cases, except where there are roots or stones.

In regard to sowing on a stale furrow, it is a good practice in breaking up old ley, when done in soils that are not ticklish to get upon. On wet clays and loams, where not well drained, the business of sowing is often obliged to be delayed too late in the spring, if ploughed in the winter, in which cases it is safer to plough and dibble at once; but on other sorts dry enough, such as dry loams, sands and chalk, it is better to plough in autumn and plant early in the spring: the frosts and successive variations of weather, sweeten the freshly turned up soil, and crumble the surface enough to give a little mould, and not so much as to impede the person employed in dibbling.

But in all the heavy strong sorts of land a great improvement has been effected by ploughing the lands in the early autumn, so as to avoid as much as possible all spring tillage. In this way the summer fallows intended for barley and oat crops; the pea, bean, and tare stubbles which are to receive the same sorts of crops, as well as the white corn stubbles which are designed for any sort of spring crops, should at this season be ploughed in a careful manner in the proper form, so as to be the future seed earth, no further ploughings being admissible on any account. In this method, it is stated, in the Calendar of Husbandry just noticed, that the crops are much larger and the expense considerably lessened. The leading principle is this; if the land is so laid in autumn, on to ridges of that exact breadth which suits the tools, (whatever they may be, whether harrows, scarifiers, scufflers, or drills,) so that the horses which draw them may walk only in the furrows, the frosts will have left so fine and friable a surface, that any of these operations may be performed long before the land in the common system would be ploughed. The seed is usually in the ground before the old fashioned farmer thinks of moving. If he ploughs, he turns down a dry crumbling surface, and brings up the stiff wet *clung* bottom; if rain comes, then he is in the mire, and must wait for a season; if a drying sharp north-east wind comes, his furrows are converted to oblong stripes of a stony hardness. In one case he is plagued with mud, in the other with impenetrable clods; he was possessed of just the surface he wanted, and which, once lost, is not often regained. This surface may be scuffed, and immediately drilled securely. In this practice the lands or ridges should be laid out with great exactness and attention.

There are also other points that require attention in the ploughing of land; the furrow-slices should be disposed in a different manner, according to the nature of the grounds;

the

PLOUGHING.

the views of the farmer and the crops to be grown upon them, circumstances which have been already noticed in speaking of *ploughs*. The feed furrows, and those where advantage is to be derived from the effects of the atmosphere, should be laid much less flat than in other cases. The breadth of the furrow must likewise be regulated by similar circumstances. And there is another point that has been noticed by Mr. Kent, which is, that, on all the lighter sorts of soils, it is essential to preserve at the depth of from six to eight inches below the surface of the land, what in the language of farmers is denominated a *pan*, which is an unbroken bottom at such depth; in consequence of which, it is supposed, that manure may be kept longer in the top part; and that in such seasons as are very dry, the less deep this pan is, the less liable the grain will be to burn, especially where it consists of earth and not of rock, as the roots of the grain will find more moisture by striking against a body of compact earth, than in a greater depth of hollow earth, as the former obviously preserves more moisture in such dry seasons. There is also another advantage in this pan, which is, the having a less proportion of mould to work and keep in a state of fertility. In such cases, where deep ploughing is had recourse to, this compact bottom or pan must be broken and destroyed, for which a great deal more manure will become requisite to keep the land in proper condition for the supporting of crops. On these accounts, care should be taken in such cases, not to go so deep with the plough as to injure this firm earthy crust, and increase the difficulty of cultivating such soils. See PAN.

In regard to the frequency of ploughing lands, it must, in a great measure, be directed by the state or condition in which they are, and the nature of the crops which are to be grown upon them. It has been observed, in a late System of Practical Husbandry, that the stiff, clayey, loamy, and even chalky soils will, in general, stand in need of more frequent stirring, either by means of the plough, harrow, or some other implement, in order to separate and break down their tenacious particles, than those of the sandy or gravelly, and more light kinds, in which there is much less adhesion. Besides, where lands have been in a course of tillage for some length of time, whether they are of a clayey, loamy, or even sandy quality, they may require less frequent stirring than where the contrary is the case. And where the method of putting the seed into the ground by means of drill machines is to be had recourse to, a fine state of tilth will, in general, be indispensably necessary. But, the nature of the crop that is to be cultivated must, in most cases, direct the number of ploughings that may be necessary; as some demand a much finer state of tillage than others; though in most cases a well reduced earth is favourable. It has, indeed, been asserted by Mr. Tull, in his Horse-hoing Husbandry, that the finer land of any kind is made by tillage, the richer, and more capable of supporting plants it becomes. A proof of which may often be met with in lands where a part has, from accident or other causes, been better tilled than the rest, as, though they be afterwards constantly managed in precisely the same manner, the part so treated always affords better crops than those which have not had the advantage of such tillage.

And where the nature of the crop is such as to be greatly retarded and injured in its growth, by the occurrence of other plants, as in wheat and barley, the land will constantly require to be rendered fine and mellow, either by frequent stirring by the plough, or the growing of such preparatory crops as have a tendency to bring it into a friable and clean state, by the shade which they produce, and the repeated tillage and culture which they receive

while growing. Also, where such plants as produce large, knobby, or tap roots, in or upon the soil, are to be grown, it will be necessary to have the land well broken down, and rendered mellow by repeated turning over, in order that they may more readily push down, or extend themselves in other directions. It has likewise been found, that a fine state of tilth is always the most favourable for affording the nourishment and support of crops in a free and equal manner, both on account of its admitting the fibrous roots of the plants to spread and extend themselves with more facility, and the manures to become more minutely divided, and more intimately blended with the soils; as well as from the substances that constitute the food of the plants being more readily and more copiously formed by the chemical combinations and decompositions that take place under such circumstances. And further, by means of such degrees of pulverisation and mellowness, the seed, especially when it is of the smaller kind, is not only more equally and more perfectly covered, but its vegetation more quick, from its becoming more fully in contact with the mould, and from the moisture being more minutely diffused and retained in the ground, which is an advantage of much importance in the cultivation of many sorts of crops.

The work of ploughing may, in most cases, be well performed with any of the light well formed ploughs that have been described, with two horses without a driver, being managed by reins by the ploughman; and where double ploughs are employed, three horses may mostly be sufficient for effecting the purpose, being directed in the same manner; though in the usual method of performing the work, with the common awkward ill-formed ploughs, in practice in many places, three, four, or more horses are in general made use of, and the business executed with more difficulty and less dispatch. The advantage of having recourse to the improved sorts of ploughs in this expensive sort of work, must, of course, be extremely obvious. It has been stated, in the third volume of Communications to the Board of Agriculture, that it has been lately found in Lancashire, that in a light loamy sort of soil, Small's plough with two horses abreast, and the ploughman driving them by means of reins, is capable of executing its work with equal expedition, and to a better depth when necessary, than the common ploughs of the district with four horses, a ploughman, and a boy as driver. This great advantage is considered as depending upon the excellence of its construction, and the team possessing the greatest purchase in the draught, by being placed so near the plough; the least variation in the formation or proportional distances of the different parts being, however, capable of destroying the effect. The Northumberland or Cumberland, and the Rotherham ploughs are also found equally valuable.

Having taken this view of the nature of performing this important operation in the cultivation of land, it may be useful to state the facts as they have been collected in the best arable districts of the kingdom, by the surveyors employed by the Board of Agriculture. In West Norfolk, as stated by the secretary to the Board, there is much difference in performing the work. On some farms he has remarked, the furrow to be cut flat and clean; but, on others, *wrist-baulked*, by tilting the plough to the left, which, raising the share-fin makes that inequality, and is partly the occasion of his having found so many ploughs at work, which would not go a single minute without holding. In East Norfolk, Mr. Marshall has observed, that the ploughman, to prevent the soil when moist from turning in whole glossy furrows, which they term "scoring," ties a piece of strong rope yarn round the plate or mould-board, which by these

PLOUGHING.

means is prevented from acting as a trowel upon the soil. And Mr. Young found this the practice at present; but was informed, that it was not so generally wanted as formerly, which they attributed to better constructed *plates* or mould-boards.

And in relation to the depths of ploughing, he states, that Mr. Thurtell, at Gorlstone near Yarmouth, has a great opinion of deep ploughing. Three or four inches are a common depth about him, but when land is clean he always ploughs five, and sometimes six or seven; he is careful, however, not to do this on foul land; he has no apprehension of breaking the pan, having many times gone deep enough for that without any inconvenience, and as to bringing up a dead soil he has not seen any ill effects from it. The land on which this practice has been pursued, is a good sandy loam on a clay marle or gravel bottom. But Mr. Everitt, of Caistor, is of a different opinion; he is not fond of deep ploughing; he thinks four inches deep enough: his ideas on this subject, however, seem, Mr. Young says, to have been chiefly the result of a trial made by his father, who broke the *pan* by trench-ploughing a piece of land, which has ever since been full of charlock, &c. The difference of their soils will not, he thinks, account for this opposition of sentiment. Gorlstone is a very good sandy loam at 20s. or 25s. an acre, though certainly inferior in depth and goodness to the land at Caistor. In discourse with these two gentlemen on this subject, Mr. Everitt remarked to Mr. Thurtell, that if he ploughed deeper than common, he ought to add manure proportionably to the quantity of soil stirred; an old idea of his, and he remembers well, combated by his friend Arbuthnot. It is added, that Mr. Francis, of Martham, ploughs four or five inches deep: and Mr. Cubit, of Honing, on a fine sandy loam, always as shallow as possible; and at East Ruffon, where the soil is exceedingly good, the same; he thinks a smaller quantity of muck by this means answers. But they do not plough four inches deep at Scotto; Mr. Dyble remarked, it is observed, that a piece was there ploughed five or six inches deep, and damaged for seven years; three inches enough; the soil much of it a fine sandy loam, manifesting no want of depth. Mr. Palgrave, at Collishal, however, applies deep ploughing in one case with singular judgment; he brings by water from Yarmouth large quantities of sea ooze, or haven mud; this, on dry scalding gravels and sands, he trench-ploughs in without fear of burying, and finds, on experience, the effect very great, forming thus a cool bottom, so that the surface burns no more. And Mr. Johnson, of Thurning, thinks that it is common to plough too shallow; nor does he believe that any mischief results from depth. He has made a ditch one year, and thrown it down again the next, and the benefit was seen for seven years, without the soil being acted on by draining, or wanting it; nor is he nice to have his muck ploughed in shallow, having no fear of burying it. By ploughing a good pitch for turnips, they come slow to the hoe, but when they do get hold, thrive much faster than others. He also finds Mr. Reeve, of Wight, an advocate for deep ploughing; he goes five inches deep; if he did not he should get no turnips. And Mr. Duffgate approves of deep ploughing; remarking, that he breaks up his *ollonds* deeper than most people. Mr. Willis observing the marle on his land was sunk below the common path of the plough, turned it up again by going a deeper pitch, and found it to answer nearly as well as a new marling; and he suffered no inconvenience. It is added, that the two-furrow work about Holt, &c. is to turn a furrow on lay or *ollond*; the plough then returns and throws it back with the untouched

land that is under it, into the former open furrow, and overlapping that, rests on the baulk left beside it. It is also observed, that Mr. Money Hill, in breaking up the strongest land he has, ploughs deeper than on the lighter; that is, four inches, and on light three and a half; and on that depth drills on flag; if twitch in the land, ploughs only three and a half; if beyond the usual depth, would hurt the crop and give weeds. Waterden is a thin and flinty soil. It is remarked, that Mr. Hill's father lived for many years at Gatefon, and was succeeded in the farm by Mr. Parker. Mr. Hill's last crop yielded 400 lafts of corn, above 320 of which were barley. He generally ploughed four inches deep, and never more than four and a half. Mr. Parker in the first year ploughed the second barley earth seven inches deep, sowing about eight score acres (the common quantity twelve score.) He sold that year but twenty lafts; the feeds also were worse than usual; the wheat that followed, good; but in general, he had indifferent crops for fourteen or fifteen years. And in March he applies what he calls *one-furrow* work to a foul stubble, if he has such by chance; the land side horse (that on the left hand) always, after the first furrow, returns in it; it is left open; harrowed down with a heavy harrow; then the weeds gathered and burnt, and the next ploughing given across. Norfolk Corrected Agricultural Report.

The Agricultural Report of Hertfordshire states, that the common depth of ploughing about Westmill is four or five inches; but Mr. Greg ploughs as deep as the staple will admit; which account of his bailiff implies, that five inches are not the depth of the staple. The crops in that vicinity are so great, that the writer should suppose that there cannot be any material error in the basis of their practice. And Mr. Whittington remarks, that winter tillage is but of little use: he avoids it as much as possible, and has found that the application of a break, or a large four-horse harrow, is a good substitute for some ploughing.

With regard to the strength of team which is necessary, it is stated by the author of the Norfolk Report, that Mr. Thurtell, through the summer, ploughs with three horses two acres a day, one always resting: this from finishing sowing spring corn to the end of the turnip tillage. There is no doubt of their ploughing with ease an acre in four hours and a half. And in the clays of Marshland, all are foot or swing-ploughs; never more than two horses used: they do an acre a day, and in summer one and a half at two journies. And at Remsby, each pair of horses two acres a day at two journies.

About thirty years ago, the common price of ploughing was 2s. 6d. an acre, in every part of the district, except Marshland: it is now 4s.; in some places 3s. 6d. Mr. Young adds, that the farmers in every part of it get more land ploughed in a day, by their own men and horses, than on any similar soil in any other part of the kingdom; which, he thinks, is not altogether to be attributed to the merits of the plough, though it is certainly a good one, nor to any superior activity in the horses: the cause is more in the men, who have been accustomed to keep their horses and themselves to a quick step, instead of the slow one common in almost every other district of the island.

And the Suffolk Report states, that in every part of the county this sort of work is done with a pair of horses, conducted with reins by the ploughman; and the quantity of land usually turned in a day is an acre upon stiff soils, and from one and a quarter to one and a half on sands. And it is added, that the ploughmen are remarkable for straight furrows, and also for drawing them by the eye to any object, usually a stick whitened by peeling, either for water

cuts,

PLOUGHING.

cuts, or for new laying out broad ridges, called there *flatches*; and a favourite amusement is ploughing such furrows, as candidates for a hat, or pair of breeches, given by ale-house keepers; or subscribed among themselves, as a prize for the straightest furrow. The skill of many of them in this work is remarkable. Such a mode should be practised in other districts of the kingdom.

In the Hertfordshire Report it is remarked, that the price of ploughing about Hatfield amounts to 11s. and 12s. an acre; twenty years ago, 7s. were paid; all is done with four horses and a driver: 20s. *per acre* have been paid in the new inclosure at Cheshunt. And that in the 17 acres of experiment ground of the marchioness of Salisbury, the cultivation was began by a powerful trench ploughing, 18 inches deep. Mr. Stephenson, the manager, who, having been bred a gardener, had the farmer's best education, knew that her ladyship intended to cultivate parsnips, carrots, cabbages, and other plants-demanding deep tillage, and very wisely began on garden principles. He remarks, that in general, in Hertfordshire, there is a deficiency in not ploughing to a greater depth: they have a prejudice against it, and think land ruined that is stirred deeper than common. It is admitted that the first crop will sometimes suffer in spots, but the succeeding ones make ample amends. Barley has been sown on trench-ploughing, and with success; in a dry season it grew well, while that for which the land had been indifferently prepared stood still.

Mr. Pratchet of Hatfield having asserted that he would readily give for ploughing his land once over 12s. *per acre*, and that he was sure it cost him more, put down the particulars on which he founded his opinion, and his calculations are these:

Expences *per Week*.

	£	s.	d.
Four horses, seven bushels of oats, at 4s. -	1	8	0
Eight trusses of hay, at 5l. - - - - -	1	2	2
Ploughman - - - - -	0	15	0
Driver - - - - -	0	12	0
Wear and tear, plough and harness - - -	0	6	0
	4	3	2

It is added, that they plough five roods *per day*, when they break up their land, and one acre and a half when they give it a second, or any subsequent ploughing; and that at seven acres and a half *per week*, the expence amounts to 11s. and 1d. *per acre*, besides the wear of the horses; at nine acres, it amounts to 9s. 2½d. But the above estimate of Mr. Pratchet is drawn from the consideration, that this includes none of the time when the horses are unemployed, which is a very material point, and adds largely to the expence when they work; on a wet-land farm particularly, the time thus lost is considerable.

Mr. Cook, from near Colchester in Essex, bailiff to the duke of Bridgewater, is of opinion, however prejudiced in favour of two-horse ploughs, that they could not break up for a fallow the stony clayey loams of this county; but that, after one ploughing, they are fully equal to the following tillage. And that about Hitchin, they break up with the common Hertfordshire plough; but in stirring, use the swing-plough with three horses, and sometimes with two. And that at Mortgrave, near Hitchin, where Mr. Green is settled, who came from near Clare, in Suffolk, about four years ago, this farmer never uses more than two horses in a plough, and does his work just as well as the

others with four: he succeeds, and is supposed to be a very thriving man. Some of his Suffolk ideas, however, are, Mr. Young observes, said not to have answered so well, particularly the making composts with ditch earth: this he has given up, and now goes to London for manure, like others. And Mr. Sedgewick recommends a practice in ploughing broad lands with the common plough, to leave two or four furrows for the small narrow plough, to finish the lands; by which means, there are channels on the slopes of the open thoroughfs to catch feeds; whereas, with the great plough, the feed rolls into those thoroughfs. But Mr. Parker of Munden uses the foot-plough of Middlesex, as preferable to the great Hertfordshire wheel-plough, and can break up stony strong land with it as well as the other performs it. Cases very rarely happen, in which the county plough has the advantage. He has a great opinion of deep ploughing; never has the least objection to any depth, nor ever yet checked his men for going too deep. His common depth is nine inches. This he has practised 23 years on good loamy land in Huntingdonshire, and here on the gravels and flints of Hertfordshire. He has never lost a crop by it, but met with an unvarying success; and is clearly of opinion, that at this time of day it ought not to be made a question, but received as an admitted fact. He does not limit his ploughs to nine inches, for he would like twelve better, if easily attainable. It is added, that he has no idea of burying dung, but ploughs it in nine inches deep, and would plough it in deeper; for he is well assured from experience, that nothing is lost: and a great advantage of depth is, that one ploughing, given deeply and clean, is of more effect and better than two, or even than ten, such scratchings as are called ploughings often in this county; but the harrows in *cleaning* should, on loamy soil, be as deep as the ploughing. Mr. King of Barkway, it is remarked, who has Suffolk connections, ploughs with a pair of horses and no driver, and does as much and as well as his neighbours with four.

On their most retentive clays at Albury they are extremely attentive never to go on in wet weather: the soil is stiff and ticklish, and if touched when too moist, is greatly injured. This is a fact which is very general in most parts of the kingdom, on such lands.

In every part of Hertfordshire they have a method of ploughing, of which they are very fond, called *combing*, or *backing*. A field that lies on flat or broad lands is half ploughed across, by beginning with a furrow, and returning; the plough doubles the breadth of it by a second furrow, the contrary way from the former, leaving a very small baulk, just sufficient to give steadiness to the plough, by a purchase against the unturned land, which is equally well effected by leaving no baulk, but by going two inches deeper on the land side. Then the plough, returning for the third time, throws back the last turned furrow, taking up earth enough under it to clean plough the whole land, if wanted, or to do it at such spaces as to whole plough, or half plough the field; but if combed close, the surface is left in regular narrow ridges, called *combs*. This operation, with a little difference in the execution, is called *ribbling* in Suffolk. It appears a good hold for the harrows. The writer of the Hertfordshire Report saw it well executed at Sir John Seabright's, at Beechwood, who understands the Hertfordshire tillage well. And *bouting*, as it is called, is the lapping of two furrows together, by forming narrow ridges, a bout in each; then they are reversed in the same manner by splitting; after that, they plough down by one furrow in the centre of the ridge, and so leave it for har-

PLOWING.

rowing: some time elapses between each operation. In breaking up, they do an acre a day, and sometimes more.

It is stated in the Corrected Report of the County of Essex, that the ploughs which are employed there are both those of the swing and wheeled kinds; the latter generally on dry land, and the former on wet: but that in some districts, swing-ploughs are used on all soils. That in general the plough-team is two horses, driven by the ploughman by means of a cord; and that a common addition is a perpendicular iron fastened to the beam, with two holes to keep the cord from entangling with the plough or whippetrees. But that upon strong land, three horses abreast are not uncommon, when the work is hard, though still without a driver. Further, that the usual day's work is an acre; at busy seasons, and for good managers, five roods are sometimes done. Scarcely any common farmers use oxen; there are such cases, but they are very few: some gentlemen have them. The ploughing is in general extremely well performed in this county, which abounds with skilful and accurate ploughmen. The reporter has walked over 40 acres of wheat fresh put in, eyeing the land carefully, and not discovering a single false furrow; no variations in the breadths of the stiches, or of the furrows; no depressions, nor any variations in the curvatures of the stiches. But they do not plough so deep as in Kent, nor so flat as in Norfolk; nor is it their wish to do so. The number of ploughings for different crops are in most places great, as from four to eight, or more; and as to the depth of ploughing, some prefer it when done deep, others when more shallow. In the island of Foulness, they break up for fallows six to seven inches deep; but some farmers shallower. Mr. Vassal of Eastwood, in Rochford hundred, ploughs eight or nine inches deep; and Mr. Wood, who managed Rochford-hall, after the death of the late Mr. Wright, trench-ploughed several fields, which were the worse for it, relative to the wire-worm. The present Mr. Wright ploughs his fallows only a fair depth, and is convinced that it is better, as he has had much better crops from shallow tillage. A neighbour of his, after ten years of deep ploughing, got at first nothing from it but weeds and wire-worm. Wild oats abounded much. He left off the practice, and then got much better crops.

At Little Wakering, Dr. Asplin, and many others, plough the first earth of a fallow very shallow, and get deeper every time; other earths, not in fallowing, shallow. But as to the depth of ploughing for fallows, it must depend upon the soil; but the best farmers like to go deep enough to chip up the dead soil now and then, and shew it a little upon the surface, after all is finished.

In the work of ploughing here, some think the laying the furrows flat the best; but others prefer feather-edged furrows, as covering the seed better in harrowing; and this is the more general opinion. At Burnham, Mr. Ketcher does not approve of feather-edged ploughing; and he thinks flat furrows best on wet land, as well as on dry. But Mr. Tabrum, at Margaretting, not only approves feather-edged work, but thinks it essential for giving moulds to cover the seed.

In regard to the expence of ploughing in this district, in all the strong rich clays at Bradfield, and around by the coast to Clackton, it is 8s. an acre. On the wet loams at Dunmow, three horses, a man, and boy, for the first and second earths of a fallow, by the acre, 7s. At Snorum, from 8s. to 9s. each ploughing; the soil very stiff. Mr. Rush, at Latchingdon, gives 9s.; at Rochford, 10s. 6d.; at Raleigh it was formerly 5s., is now 8s.; at Thorndon,

10s.; at Margaretting, the common hiring price is 10s. 6d.; and at Toppesfield, Mr. Eley reckons it worth 8s. with three horses; 6s. 6d. with two. They plough barley-fallows five or six times.

At Little Wakering, Dr. Asplin used formerly to contract with one labourer for all the tillage of his farm, at 2s. an acre for ploughing, 6d. for harrowing, and 2d. for rolling. More work was done, always five roods ploughed *per* day, but he left it off on account of the shallowness and wide furrows.

At Jetworth, in Oxfordshire, according to the report of that district just published, they plough with four horses, and do an acre a day. In the fourth-eastern division of the county, a party of farmers agreed that an acre is the general quantity that should be ploughed in a day by a team; but many ploughs go out for three roods. The expence was thus reckoned.

	£	s.	d.
Four horses, $1\frac{1}{2}$ cwt. of hay per week, at 4s. 6d. each	1	4	0
One bushel of oats <i>per</i> horse, at 3s. 6d.	0	14	0
Chaff, 2s. <i>per</i> week	0	8	0
Decline of value	0	4	0
	2	10	0
<i>Per</i> diem	0	7	1 $\frac{1}{2}$
Wear and tear	0	2	6
Man and boy	0	2	6
	0	12	1 $\frac{1}{2}$

However, on casting up the account, they observed that it was too low, for an acre of land could not be ploughed under 14s.

At Wormsley, &c. horses are allowed 20lb. of hay *per* diem, and a bushel of oats *per* week; more for extra work. They plough with three or four, and do an acre a day. Three and four horses are likewise employed in most other places, but some have tried two, though this is only seldom done. The same quantity of land is usually ploughed in the day.

About Adderbury, it has been agreed by several very good farmers, that it is right to plough a stubble in autumn for a fallow, deep; five inches considered as deep ploughing. Also at and about Thumley, they are of the same opinion, when they break up for the first time in May. Mr. Edmonds thinks, that beans do best on deep ploughing; but the after crops may suffer for want of due tillage being given to such additional depth. If deep, it should be continued. Mr. Cozins, of Golder, ploughs eight inches deep for beans, and also in the first ploughing for a fallow. Mr. Newton, of Crowmarsh, likewise ploughs deep for beans and turnips; but thinks that clover land cannot be ploughed too shallow for wheat. At Mungwell, the bishop of Durham ploughs for the most part according to the staple of the ground, which is very shallow. He generally goes as deep as the staple will admit. His lordship gained exceedingly by ploughing one inch deeper than the farmer before him had done; and which has gradually become an addition to the staple and the soil.

Mr. Percy thinks, that they are apt to plough too much; the less they plough their land the better. A good farmer will plough enough to keep it clean, and all beyond that is bad. Hence, it is supposed, that land may be ploughed too much.

On

On the rich sands at Adderbury, they do not plough more than four inches deep at any time, except on the little clay land they have, at the first breaking a fallow.

Mr. Davy of Dorchester ploughs as deep as he can for beans; but as shallow as possible on clover lays for wheat.

The rates of ploughing in most of the other districts, both in the south and the northern parts of the kingdom, stand equally high with these; and in some they are considerably higher, as more strength of team is employed.

There are many other modes of ploughing practised in different counties, but it is not necessary to describe them here. See TILLAGE.

PLOUGHING in Green Crops, the process of turning down various sorts of vegetable crops in their green or moist succulent condition. It is a method of practice that has been employed for a great length of time on the continent, though little practised here by the farmers. The reason of which is probably, that the soils are in most districts too wet and heavy for its being had recourse to with advantage; the light and more friable kinds of land are most adapted for improvement in this way, as in such the green materials undergo decomposition much more readily, and become more quickly in the proper state for affording the support of crops. In some clayey soils, the putrefaction of such materials is retarded in such a way, that little or no benefit can be derived from their use. But in suitable soils, crops of the green kind, such as buck-wheat, tares, clover, rape, and where sown for the purpose, pease or beans, &c. may be used with advantage, being turned in as a preparation for wheat-crops, without the expence of a fallow. Where employed in this way, the crops, as observed above, should always be turned down when in their most luxuriant state of growth, and the soil rather dry, in order that a speedy decomposition and decay may be undergone. It has been suggested, that advantages may be gained in this view, by the application of small proportions of calcareous substances in their caustic or more active state over them before they are turned down. And that the economy of this practice must chiefly depend upon the savings in cartage, and the labour of preparation, which in other sorts of manure is often very heavy. Mr. Young, in his Survey of Lincolnshire, states, that this practice, after having been attempted, appears to have been given up from its not fully answering the purposes for which it was intended, probably for the reasons stated above. But it is a mode of husbandry that Mr. Donaldson states to have been had recourse to with success in Warwickshire, and which he considers as, beyond all others, the most economical. The expence of the seeds is almost the whole of what attends the practice. It is now little had recourse to any where.

In the county of Essex, Mr. Hardy, of Bradfield, had a field of clover, part of which was mown twice, and part but once; the second growth being kept until it was in blossom before feeding, when hogs, &c. were turned in, who trampled down five times as much as they ate, which was ploughed in for wheat: and where this latter management took place, gave by far the flouter wheat: and it is said, that it should be remarked that through all the parts of Tending hundred, this husbandry of trampling second crop clover apparently to waste is very general, and the opinion entertained of its merit is high. Lord Braybrook sows cole for ploughing in November, and his bailiff, Mr. Nockold, assured the reporter that he could see to an inch in the barley where this management takes place. If the crop be high he mows it first, but this is for want of a skim-coulter, which would do it better standing. Mr. Clayden, a very spirited tenant on the Audley-End estate, is in the same hus-

bandry. Corrected Agricultural Report of the County of Essex.

Ploughing in green crops is frequently practised by some of the best farmers bordering on the White-horse hills, in Berkshire, and found much less expensive than carrying dung from the yard. Vetches, buck-wheat, rye, &c. are there chiefly employed for this purpose. Corrected Berkshire Report.

PLOUGHMAN, in *Husbandry*, the person who guides the plough, in the operation of tilling or tillage.

PLOUGHMAN'S Spikenard, the English name of a genus of plants called by the botanists *conyza*; it is likewise called by us *flea-bane*. See **CONYZA**.

PLOUGUENAST, in *Geography*, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Loudeac; 7 miles N.N.E. of Loudeac. The place contains 3189, and the canton 12,503 inhabitants, on a territory of 132½ kilometres, in five communes.

PLOUGUERNEAU, a town of France, in the department of the Finisterre, and chief place of a canton, in the district of Brest; 13 miles N. of Brest. The place contains 6430, and the canton 15,033 inhabitants, on a territory of 152½ kilometres, in 6 communes.

PLOUHA, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brieuc; 12 miles N.N.W. of Brieuc. The place contains 4145, and the canton 10,756 inhabitants, on a territory of 125 kilometres, in 8 communes.

PLOUZEVEDE, a town of France, in the department of the Finisterre, and chief place of a canton, in the district of Morlaix; 8 miles S.W. of St. Pol de Leon. The place contains 2364, and the canton 11,436 inhabitants, on a territory of 130 kilometres, in 6 communes.

PLOWMAN'S ISLANDS, a cluster of islands, forming a part of Chu-san islands (see **CHU-SAN**), which are inhabited, and contain several spots of beautiful verdure; but not a single shrub, except a very few dwarf fruit-trees, oak, and Weymouth pine. The rocks on these isles are of the same nature with those of the Ladrões; with the addition, in some parts, of perpendicular veins of white, and of blue and white spar. The Lion, one of the ships belonging to lord Macartney's embassy, moored between the Plowman and Buffalo's Nose islands: and found a most excellent harbour, secure from all winds, and the holding ground so good, that it required the whole strength of the ship's crew, with the assistance of every purchase, to weigh the anchors: the depth of water being from 12 to 22 fathoms. The tide rises about 12 feet, and runs at the full and change of the moon, 2½ miles an hour. Its latitude is 29° 45' S., and longitude 121° 26' E. The ship was supplied from these islands, at moderate rates, with bullocks, goats, and fowls; and from some of the surrounding boats with a variety of excellent fish. Staunton's Emb. to China, vol. i.

PLOWS, in *Agriculture*, a provincial term signifying ploughed ground, either in clover or open fields.

PLUCHE, ANTONY, Abbé, in *Biography*, an elegant writer, was born at Rheims in 1688. Having passed through the usual course of education, he was appointed professor of humanity in the university of his native place, and two years afterwards of rhetoric, at which time he entered into holy orders. Some years afterwards he went to Paris, where he gave lectures in geography and history. In that capital he acquired a name among men of letters, by his popular work entitled "Spectacle de la Nature," of which the first volume appeared in 1732, and which was carried on to nine volumes. It contains a view of the most interesting facts in natural history,

history, as they were then known, in the form of dialogue. The dialogue is not well kept up, though few works have been more read, and it was translated into various languages. His next publication was "Histoire du Ciel," in two vols. 12mo., of which the first volume is chiefly mythological: the second relates to the formation of the world, and concludes with a confirmation of the Mosaic account of the creation. In 1750, he published a treatise, entitled "The Truth of the Gospel demonstrated." As a philologist, he is distinguished by his "Mecanique des Langues, et l'Art de les Enseigner," which is said to be a very useful and judicious treatise. He died in 1761, at the age of 73, leaving behind him the character of a truly virtuous and respectable man. Two of his posthumous pieces were published after his death, entitled "Concorde de la Geographie des differens Ages;" and "Harmonie des Pseaumes, et de l'Evangile."

PLUCKART BAY, in *Geography*, a S.E. branch of Loch Ewe, on the W. coast of Scotland. N. lat. 57° 45'. W. long. 5° 34'.

PLUCKENIN, a town of America, in Somerset county, New Jersey; 28 miles N. of Princeton. It carries on some trade.

PLUDENTZ, a town of Germany, and capital of a county of the same name, situated on the Ill. In 1533 it was almost destroyed by an earthquake, and in 1638 was wholly burnt down; 62 miles W. of Inspruck. N. lat. 47° 3'. E. long. 9° 8'.

PLUDESCH, a town of Germany, in the county of Pludentz; 6 miles N. of Pludentz.

PLUE, L., or *Rainy Lake*, a lake of Upper Canada, lying W. by N. of lake Superior, and E. by S. of the lake of the Woods. The Narrows are in N. lat. 49° 3' 2", Fort la Plue in 48° 35' 49", island Portage, 50° 7' 31", at the Barrier, 50° 7' 51". W. long. 95° 8' 30".

PLUE, L., a river forming a communication between lake La Plue and the lake of the Woods.

PLUG, a large wooden peg, with which to stop the bottom of a cistern, cask, pipe, or the like.

PLUG, in *Ship Building*. *Haufe-plugs* are pieces of timber trimmed to the size of the haufe-holes, so as to keep out the water. *Shot-plugs* are formed like the frustum of a cone of various sizes, in proportion to the holes made by the different sizes of shot which may penetrate the ship's sides in time of action. The latter are sometimes made of tallow and junk, or oakum, made hard together, and are thrust or driven into those shot-holes, to prevent leaking: accordingly they are always ready for this purpose.

PLUKENET, LEONARD, in *Biography*, "a learned, critical, and laborious botanist," as Dr. Pulteney justly denominates him, was the contemporary and rival of PETIVER, see that article; and laboured, with still more ardent, as well as exclusive, assiduity, to collect and to delineate the vegetable productions of nature. His origin and native country, as well as the place of his education, are unknown. He has indicated 1642 as the date of his birth, and we know that he survived the sixty-third year of his age, but there is no precise record of his decease. A handsome portrait of him, at the age of forty-eight, is prefixed to his *Phytographia*, with the title of Doctor of Physic, and his arms; ermine, a bend dexter engrailed, gules. It is not known where he took his degree. His name seems to betray a French extraction, *plus que net*, and has been latinized *plus quam nitidus*. He resided in Old Palace-yard, Westminster, where he appears to have had a small garden; but as Dr. Pulteney sought in vain for his name, in several lists of the College of Physicians, printed in the first years of the 18th century, as well as in those of the

Royal Society, of the same date, it should seem that he was not then eminent, either as a medical practitioner, or a natural philosopher. His motto, an anagram of his name, *ut penè nullus sic ardeo*, well expresses the zeal with which he devoted himself to his favourite study; while another motto in the same page, over a burning candle, *aliis inserviando consumor*, and a subsequent one, to the fourth part of his work, *nil nisi premia desunt*, evince that his worldly recompence was not adequate to his wishes or expectations. Dr. Pulteney has discovered that Plukenet had a son Richard, who was a student at Cambridge in 1696; and the *Almagestum* contains some verses written by another son, Robert, at Eton school; which is all we know of his family or connections. He published his early works at his own expence, but was assisted afterwards by trifling subscriptions. Towards the close of his life he is said to have experienced royal patronage, to have obtained the superintendency of the garden at Hampton-court, and the title of Royal Professor of Botany; all from the favour of queen Mary. Three of the sections of his *Phytographia* are severally dedicated to bishop Compton, the first earl of Portland, and king William III. That he enjoyed the friendship of Uvedale, who was his fellow-student; and the high commendation of Ray; are sufficient proofs of his personal and scientific merits. The beginning of the *Almagestum* testifies his elevated piety, which at the end degenerates into the orthodox style of the day. That he was skilled in the learned languages, and that his correspondence was very extensive, appears from almost every page of his works; and there are many particular parts which shew his researches to have been deep, and conducted with considerable ability. It is to be lamented that some of his latter pages betray a severity of stricture, on the literary labours of Sloane and Petiver more especially, of which we have already spoken in the life of the latter, and of which more may be said hereafter when we come to speak of Sloane. Plukenet was, apparently, a man of more solid learning than either of those distinguished writers, and having been less prosperous than either, he was perhaps less disposed to palliate their errors. As far as we have examined, his criticisms, however severe, are not unjust.

These are all the circumstances we can find, illustrative of the life or character of Plukenet. We shall now offer a few remarks upon his works.

Having collected a vast Herbarium, for the time in which he lived, not only by means of his various correspondents, but also from the treasures that were then daily pouring into the gardens about London, his object was to publish a catalogue of the whole, accompanied by figures of the new or rare species. The first part of this design was executed in his *Almagestum Botanicum*, which, like all his other publications, is in quarto, making a handsome volume of 404 pages, dated 1696. Its arrangement is alphabetical, according to the generic names at that time received, and adopted from Bauhin and other old authors, though not without many corrections and alterations made by himself in this department. Each plant is distinguished by a specific definition, either adopted in like manner from his predecessors, or new-modelled by himself; and all the synonyms he could collect are subjoined. No ideas of systematical arrangement seem to have entered into his contemplation, at least in the plan of this work. There are passages in his writings which shew he had occasionally thought on that subject, nor could it altogether escape a man of so much reading; but it was by no means one of his primary objects. These were rather specific distinctions of plants, their synonyms, and their history. This work is

faid

said to contain about 6000 species, of which its author supposed 500 to be new. Of those 6000, many are now considered as varieties, being merely differences founded upon colour, or on double or single flowers; but if Plukenet erred in these particulars, he erred in common with all the botanical world at that period.

The *Phytographia* of our author was anterior in date to the above work, and yet is rather to be considered as an accompaniment of the *Almagestum*. It consists of 350 plates, engraved by various hands, each plate containing figures of five, six, or more, plants, chiefly, if not altogether, done from dried specimens, with various degrees of merit. If these figures seldom rise to any great excellence of botanical precision, they are at least original, and not only free from the faults of copies, so copiously displayed in the plates of Morison and such authors, but also tolerably exempt from gross mistakes of their own. Of their beauty little can be said, but the work improves as it advances. Being so generally cited by succeeding authors, especially Linnæus, it is indispensable to every botanic library. This book came out in four parts, of which the first and second were published in 1691, the third in 1692. The plates of these have the names, and many synonyms, of each plant engraved at the bottom. The fourth part, which commences with tab. 251, and was published in 1696, wants this useful appendage, and most of its figures are destitute of any reference. They are however cited in the *Almagestum*, and some of them likewise refer to that work; but in so obscure and difficult a manner, that few persons take the trouble of searching them out, or of citing them correctly in their own publications. Those who investigate the matter, will find several plants, supposed to be of recent introduction and hitherto nowhere delineated, which were known to Plukenet; though his references are often so faulty, as to damp our ardour of enquiry, by the needless difficulties they throw in our way.

In 1700 appeared the *Mantissa*, or appendix to the *Almagestum*, consisting of 192 pages, with a copious index to both works. This publication comprehends above 1000 new plants, with numerous observations and corrections relating to the former. Some of Plukenet's criticisms display great learning; as what concerns the Gopher, or Juniper tree, of the bible, first book of Kings, chap. xix. ver. 4; though he errs in referring the Barbadoes Juniper to this oriental plant; see his *Mant.* 109. Commentators have not been sufficiently attentive to botanical geography, on many occasions.

In 1705, Plukenet published his last work, the *Amalthæum*, which is a supplement to the other two, and composed on the same plan, consisting of 216 pages, with an index, and 103 plates, some of which illustrate the plants of the *Mantissa*.

All these works were republished, with new title-pages, in 1720, and again, with a re-impression of the letter-press, in 1769, making four volumes all together. Giseke published a very incomplete Linnæan index to them at Hamburgh in 1779. The herbarium of Plukenet, containing about 8000 plants, having been bought by sir Hans Sloane, is now in the British Museum. The original manuscript of his works was given by the late Mr. Hudson to the writer of the present article. Pulteney's *Sketches of Botany*. Plukenet's Works. S.

PLUKENETIA, in *Botany*, was so named by Plumier, after Leonard Plukenet, M.D.; see the preceding article. Linnæus, in his *Critica Botanica*, p. 80, draws an analogy between the great singularity of structure in the flowers, and the peculiarity of Plukenet's character as a botanist;

which idea does not seem to us so happy as many of our great master's comparisons. Plukenet's works have no remarkable eccentricity about them, but are, on the contrary, plain matter of fact, interspersed with laborious, but sober, criticism.—*Plum. Gen.* 47. t. 13. *Linn. Gen.* 501. *Schreb.* 652. *Willd. Sp. Pl.* v. 4. 514. *Mart. Mill. Dict.* v. 3. *Sm. Nov. Act. Upfal.* v. 6. 1. *Ait. Hort. Kew.* v. 5. 324. *Juss.* 392. *Lamarck Illustr.* t. 788.—Clafs and order, *Monocchia Monadelphica*. *Nat. Ord. Tricocceæ*, *Linn. Euphorbia*, *Juss.*

Gen. Ch. Male, *Cal.* Perianth of one leaf, in four deep, ovate, acute, equal, spreading segments. *Cor.* none. *Stam.* Filaments numerous, about 20, united in an imbricated manner, awl-shaped, very short; anthers small, smooth, of two tumid furrowed lobes.

Female, on the same plant, *Cal.* Perianth inferior, of one leaf, in four deep, ovate-lanceolate, acute, equal, spreading, permanent segments. *Cor.* none. *Pist.* Germen superior, four-lobed, depressed, smooth; style very long, cylindrical, declining, four-cleft at the summit; stigmas four, capitate, globose. *Peric.* Capsule four-lobed, coated, depressed, smooth, with dilated angles, of four cells, and eight elastic valves. *Seeds* solitary, large, compressed, with veiny wrinkles.

Elf. Ch. Male, Calyx in four deep segments. Corolla none. Stamens numerous.

Female, Calyx in four deep segments. Corolla none. Germen superior. Style simple. Stigmas four, capitate. Capsule four-lobed; cells elastic, with solitary seeds.

1. *P. volubilis*. Twining Plukenetia. *Linn. Sp. Pl.* 1423. *Willd. n. 1.* *Ait. n. 1.* (*P. scandens, hederæ foliis ferratis, fructu tetragono*; *Plum. Gen.* 47. t. 13. f. 2. *IC.* 220. t. 226.)—Angles of the capsule compressed, keeled.—Native of the West Indies. Miller appears to have cultivated it at Chelsea, in 1739, but it had long been lost, till the late Hon. Mrs. Barrington received a living plant from Jamaica, which blossomed in her stove at Mungewell, near Wallingford, in 1795. The stem is twining, branched, round, leafy, smooth; the young branches alternate, axillary, downy in their upper part. *Leaves* alternate, stalked, simple, heart-shaped, pointed, about three inches long and half as wide, minutely serrated, deep green, rather roughish to the touch, naked, except a slight downiness on the ribs at the back, reticulated on both sides with copious veins, and furnished with a pair of glands at the base. *Footstalks* about one-third the length of the leaves, channelled above, downy near the extremity. *Stipulas* in pairs at the base of the footstalk, very minute, triangular, acute, smooth. *Flower-stalks* axillary, solitary, racemose, downy, square at the base, round above, generally bearing one female flower at the base; conspicuous for its quadrangular germen, thick style, above an inch long, and large globose stigmas; and above it a long compound downy cluster, of numerous small male flowers. Some branches terminate in a cluster of, partly axillary, female flowers only. All the flowers are green, and more singular than beautiful. The bracteas, scattered through the clusters, are small, ovate, acute, smooth, membranous. *Fruit* the size of a small walnut, green, depressed, with four spreading, dilated, compressed, rounded angles, the valves separating elastically at the base. *Seeds* pale brown, large, greatly compressed, lenticular, somewhat bordered, rugged with elevated veins.

2. *P. verrucosa*. Warty Plukenetia. *Sm. in Act. Upf. n. 2.* *Willd. n. 2.* (*P. volubilis*; *Linn. Suppl.* 421. *Am. Acad.* v. 8. 264.)—Angles of the capsule terminated by two tubercles.—Native of Surinam, from whence our specimens were sent to Linnæus, who inadvertently referred them

them to the above original species. The *leaves* indeed scarcely differ, except in being very minutely and distantly toothed, rather than ferrated. The *flowers* are somewhat smaller. The *capsules* differ most essentially, in being but one-fourth as large as the former, their lobes each tipped with a pair of warts, and not dilated nor keeled. The *seeds* moreover are obovate, not lenticular nor compressed.

3. *P. corniculata*. Horned Plukenetia. Sm. in Aët. Upf. n. 3. Willd. n. 3. (*Sajor volubilis, fructibus corniculatis*; Rumph. Amboin. v. 1. 193. t. 79. f. 2.)—Angles of the capsule compressed, tapering, pointed.—Rumphius describes this as found wild in the woods of the district of Baguala, in Amboina, where it is known by the name of *Uta Pela*, or *Uta Tela*. The Dutch were accustomed to cultivate it, for the sake of its leaves; which, when boiled with the milk of the cocoa-nut, prove an agreeable and delicate vegetable. Their name for the plant was *Sajor-Maccou*. The *stems* are long and slender, twining about the trunks of trees, and sending off short lateral alternate *branches*. *Leaves* much like both the foregoing, but according to the plate and description, very evidently and distinctly ferrated. Their scent is strong like elder, but their taste sweet; at least when boiled, for the natural affinities of the genus lead us to presume that none of its species can be eaten without such preparation. *Flowers* small and green. There seem to be sometimes two female ones, with a simple cluster of numerous males above them. The *fruit* is very well described by Rumphius, as resembling the starry anise, *Illicium*, except in having but four cells, sometimes only three, instead of six. "Each segment," says he, "is the size of the seed of *Ricinus*, with a very thin point, and these fruits, when ripe, fly asunder, like the *Ricinus*, with an explosion, throwing out their round, compressed, or lenticular sharp-edged *seeds*." Nothing can more precisely answer to the character of *Plukenetia*, and Linneus actually confounded the plant in question with his *P. volubilis*.

PLUM ISLAND, in *Geography*, an island on the coast of Massachusetts, about nine miles long, and half a mile broad, extending from the entrance of Ipswich river S., nearly a N. course to the mouth of Merrimack river, and separated from the main land by a narrow sound called Plum island river, which is fordable in many places at low water. It consists for the most part of sand blown into ludicrous heaps, and covered with bushes bearing the beach plum. On the N. end stand the light houses, and the remains of a wooden fort, built during the war for the defence of the harbour. On the sea-shore of this island, and on Salisbury beach, the Merrimack Humane Society has erected several small houses, furnished with fuel and other conveniences, for the relief of mariners who may be shipwrecked on this coast. The N. end lies in N. lat. 43° 4', and W. long. 7° 47'.

PLUM-Tree, in *Botany*, &c. See PRUNUS.

PLUM, American black cocoa. See CHRYSOBALANUS.

PLUM Bay. See GUALIABA.

PLUM, Jamaica, or Hog. See SPONDIAS.

PLUM, Indian date, pishamin, persimon, or pitchumon. See DIOSEYRON.

PLUM, Maiden. See CAMOCLADIA.

PLUMAGE, the feathers, or covering of birds; for the mechanism of which, see FEATHER.

PLUMAGE, in *Falconry*, is particularly understood of the feathers under a hawk's wing.

The falconers also give their hawks parcels of small feathers to make them cast: and these they call plumage.

PLUMARTIN, in *Geography*. See PLEUMARTIN.

PLUMAU, a town of Austria; seven miles N.W. of Hooen.

PLUMB, or PLUM, in matters of spicery. See CURRANTS and RAISINS.

PLUMB Island, in *Geography*, an island on the N.E. coast of Long island, in the state of New York, annexed to Southhold in Suffield county. It contains about 800 acres, and supports seven families. It is fertile, and produces wheat, corn, butter, cheese, and wool. This island, with the sandy point of Gardener's island, forms the entrance of Gardener's bay.

PLUMB Point, Great, lies on the S. coast of the island of Jamaica, and forms the S.E. limit of the peninsula of Port Royal, which shelters the harbour of Kingston. Little Plumb Point lies westward of the former, towards the town of Port Royal, on the S. side of the peninsula.

PLUMB-Line, a term among artificers for a perpendicular line.

It is thus called, because usually described by means of a plumbet.

PLUMBAGINES, in *Botany*, the fourth natural order of Jussieu's 7th class, immediately following his NYCTAGINES; see that article. The name is taken from one of the genera, and the characters are these.

Calyx tubular. *Corolla* of one or more petals, below the germen. *Stamens* definite, inserted either below the germen, or into the corolla. *Germen* one, superior; style one or many; stigma many. *Capsule* single-seeded, with many valves at the base, hood-like. *Seed* straight, inserted by a thread-like stalk into the receptacle of the germen. *Coraculum* oblong, flat, surrounded by a farinaceous albumen. *Stem* herbaceous, or somewhat shrubby. *Leaves* alternate.

The genera in Jussieu are only two, *Plumbago* and *Statice*. Mr. Brown adds *Taxanthema* and *Aegialitis*.

PLUMBAGO, a name evidently derived from *plumbum*, lead, but whether it alludes to any colouring quality in the plant, or to the hue of its foliage, critics are not agreed. The latter seems consistent with *P. europaea*, or Common Leadwort, whose leaves are of a very peculiar greyish-green. The *Polygonum Persicaria*, with dark spots on its leaves, has sometimes borne this name, for a similar reason.—Linn. Gen. 86. Schreb. 114. Willd. Sp. Pl. v. 1. 837. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 323. Brown Prodr. Nov. Holl. v. 1. 425. Sm. Prodr. Fl. Græc. Sibth. v. 1. 131. Juss. 92. Tourn. t. 58. Lamarck Illustr. t. 105. Gærtn. t. 50.—Class and order, *Pentandria Monogynia*. Nat. Ord. undetermined by Linneus. *Plumbagines*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, ovate-oblong, tubular, with five plaits or angles, and five teeth, rough, permanent. *Cor.* of one petal, funnel-shaped; tube cylindrical, contracted upwards, longer than the calyx; limb in five ovate, rather spreading, segments. *Stam.* Filaments five, awl-shaped, unconnected with the corolla, enclosed within its tube; anthers small, oblong, versatile. *Pist.* Germen superior, ovate, very small; style simple, the length of the tube; stigmas five, slender, simple. *Peric.* Capsule ovate, thin, of one cell and five incomplete valves. *Seed* solitary, ovate.

Obs. We find no traces of the nectary, or valves supporting the stamens, described by Linneus.

Ess. Ch. Corolla funnel-shaped. Stamens inserted into the receptacle. Stigmas five. Capsule membranous, of one cell. Seed solitary.

1. *P. europaea*. Common Lead-wort. Linn. Sp. Pl. 215. Sm. Fl. Græc. Sibth. t. 191, unpubl. (P. Plinii; Ger. Em. 1254. Tripolium Dioscoridis; Column. Ecphr.

160. t. 161.)—Leaves clasping the stem, lanceolate-oblong, rough. Stem straight, erect.—Native of the fourth of Europe. Perennial and hardy in our gardens, but not in general cultivation. The stem is herbaceous, three feet high, upright, leafy, furrowed, with many straight upright flowering branches, each terminating in a simple dense spike, of small pale-purple flowers with a brittle calyx. The leaves are alternate, numerous, recurved, oblong-lanceolate, obtuse, bluntly toothed, dull green, rough but not hairy; their base tapering, then dilated round the stem or branch.

2. *P. lapathifolia*. Dock-leaved Lead-wort. Willd. n. 2. (*P. orientalis*, *lapathi folio*, flore minore albido; Tourn. Cor. 7.)—"Leaves clasping the stem, lanceolate, smooth. Stem divaricated."—Native of Iberia. Stem taller, with longer more spreading branches; leaves much larger, smooth; flowers about half the size of the foregoing. Willd.

3. *P. capensis*. Cape Lead-wort. Thunb. Prodr. 33. Willd. n. 3.—"Leaves stalked, oblong, nearly entire; glaucous beneath. Stem erect." Thunb.—Native of the Cape of Good Hope.

4. *P. zeylanica*. Ceylon-Lead-wort. Linn. Sp. Pl. 215. Willd. n. 4. Ait. n. 2. Brown n. 1. (*Lychnis indica* spicata, *ocymaetri foliis*, fructibus lappaceis oblongis, radice urente; Comm. Hort. v. 2. 169. t. 85.)—Leaves stalked, oblong-ovate, smooth, entire. Stem erect, round.—Native of the East Indies, and New Holland. It flowers in the stove from April to September. The stem is rather shrubby. Flowers white; with a long tube.

5. *P. rosea*. Rose-coloured Lead-wort. Linn. Sp. Pl. 215. Willd. n. 5. Ait. n. 3. Curt. Mag. t. 230. (*Radix vesicatoria*; Rumph. Amboin. v. 6. 453. t. 168.)—Leaves stalked, ovate, smooth, somewhat toothed. Joints of the stem tumid.—Native of the East Indies; said to have been introduced by Dr. Fothergill in 1777. It blooms in the stove almost all the year long; and is the most favourite species of its genus, on account of the delicate pale scarlet of its flowers, which form compound clusters at the ends of the branches. The stem is shrubby, four or five feet high, slender, and requiring support. Leaves recurved.

6. *P. scandens*. Climbing Lead-wort. Linn. Sp. Pl. 215. Willd. n. 6. Ait. n. 4. (*Dentellaria lychnioides* sylvatica scandens, flore albo; Sloane Jam. v. 1. 211. t. 133. f. 1.)—Leaves stalked, ovate, smooth. Stem zigzag, climbing. Native of the West Indies. It was brought into the stoves of this country very early, but is not much regarded at present, the flowers being white and not striking in their appearance. Sloane compares them to the common field Campion. The climbing, much more lofty stem, distinguishes it from the two last. Their leaves are variable, and afford no well-marked distinction.

7. *P. auriculata*. Auricled Lead-wort. Lamarck Dict. v. 2. 270. Willd. n. 7.—Leaves stalked, ovate-oblong, with scaly dots beneath. Footstalks auricled at their base, and clasping the stem.—Native of the East Indies. Stem shrubby, slender. Leaves obtuse, smooth above; contracted at their base. Flowers in short terminal spikes, resembling those of *P. rosea* in form, but in the dried specimen they had no appearance of a red colour. Lamarck.

8. *P. triflis*. Dark-flowered Lead-wort. Ait. n. 5.—"Leaves obovate, abrupt, smooth.—Native of the Cape of Good Hope, from whence it was sent to Kew by Mr. Masson, in 1792. This is a greenhouse shrub, flowering in May and June. We have seen no specimens of these two last species.

PLUMBAGO, in Gardening, contains plants of the herbaceous, flowering, perennial kinds, of which the species cultivated are; the European leadwort (*P. europæa*); the

Ceylon leadwort (*P. zeylanica*); the rose-coloured leadwort (*P. rosea*); and the climbing leadwort (*P. scandens*).

Method of Culture.—The first sort is increased by parting the roots in the autumn, when the stems decay, and planting them in a dry soil. They should afterwards be kept clean from weeds, and have proper support.

The three other sorts should be raised from seeds, which should be sown in pots in the spring, and plunged in hot-beds. They likewise may sometimes be raised by planting slips and cuttings in pots, and plunging them in the same sorts of hot-beds.

These are all ornamental flowering plants; the first in the pleasure-grounds, and the others in pots among hot-house collections.

PLUMBAGO, in Metallurgy, a metalline recement, separated in the purification of gold or silver with lead, and sticking to the sides of the furnace.

This is otherwise called *molybdæna*; and has the same virtue with litharge. See MOLYBDÆNA.

PLUMBAGO seems to have been used, among the Ancients, for Black LEAD (which see), and employed in making pencils for designing, &c.

The black lead used for this purpose, called "plumbago," and also "carbure of iron," by Werner "graphit," the "fer carbure" of Haüy, is a species of coal, or mineral carbon (see COAL), of a dark iron black colour, passing into steel-grey, and occurs in mass, in kidney-shaped lumps, and disseminated. It has a glittering metallic lustre; its fracture is small, somewhat curved foliated, approaching to scaly, or granular uneven: in the great it is slaty. It occurs generally in granular or scaly distinct concretions; takes a polish by cutting or rubbing; gives a dark lead-grey streak, and is unctuous to the feel, soft, and not very brittle. Spec. grav. 1.98 to 2.26. It does not flame when heated, nor can by itself support combustion. After long exposure to a high heat in a muffle, its carbon is burnt off, and its earthy and metallic part remains behind. If one part of plumbago, and two of very caustic dry alkaline, be heated in a retort with the pneumatoc-chemical apparatus, the alkaline becomes effervescent, hydrogenous gas is obtained, and the plumbago disappears. This experiment proves, that the small quantity of water contained in the salt is decomposed, and that its oxygen, by combining with the carbon of plumbago, forms the carbonic acid. The sulphuric acid does not act upon plumbago, according to Scheele. Pelletier has observed, that 100 grains of plumbago, and four ounces of oil of vitriol, being digested in the cold for several months, the acid acquired a green colour, and the property of congealing by a very slight degree of cold. The sulphuric acid distilled from plumbago passes to the state of the sulphureous acid; at the same time that carbonic acid is obtained, and an oxyd of iron is left in the retort. The nitric acid has no action upon plumbago, unless it be impure. The muriatic acid dissolves the iron and clay which contaminate native plumbago. Messrs. Berthollet and Scheele availed themselves of this method to purify it. The liquor being decanted after digestion upon the plumbago, the residue is then washed and submitted to distillation to separate the sulphur. The muriatic acid alone has no action upon plumbago, but the oxygenated muriatic acid dissolves it; the result being a true combustion effected by the oxygen of the acid, and the carbon of the plumbago. If ten parts of the nitrate of pot-ash be fused in a crucible, and one part of plumbago be thrown upon it by a little at a time, the salt will deflagrate, and the plumbago will be destroyed. The matter which remains in the crucible consists of very effervescent

alkali, and a small portion of martial ochre. If plumbago be distilled with muriate of ammonia, the muriate sublimes, coloured by the iron. All these facts prove that plumbago is a peculiar combustible substance, a true charcoal combined with a martial basis. The purer kind of plumbago, according to Scheele and Berthollet, consists of about 90 per cent. of carbon and 10 of iron. An impure kind from Pluffier afforded Vauquelin

23 carbon
2 iron
37 alumine
38 silix

100

The brilliant charcoal of certain vegetable substances, more especially when formed by distillation in close vessels, possesses all the characters of plumbago: and the charcoal of animal substances, possesses characters still more peculiarly resembling it. When animal substances are distilled by a strong fire, a very fine powder sublimes, which attaches itself to the inner part of the neck of the retort. This substance may be made into excellent black-lead pencils. Carbon may be formed in the earth by the decomposition of wood, together with pyrites; but the origin of plumbago, says M. Chaptal, is principally owing to the ligneous, and truly indecomposable, part of the wood, which resists the destructive action of water in its decomposition of vegetable substances. This mineral is found in primitive and transition rocks in England, Scotland, France, Spain, Germany, America, &c. Besides its use for pencils, the best for this purpose is that from Borrowdale, in Cumberland; it is sometimes used to lubricate machinery instead of oil, and to protect iron from rust. The hearths and plates of chimnies and other utensils, which appear very bright, owe their colour to plumbago. For this purpose Homberg long ago, viz. in 1699, directed 8lbs. of hog's-lard to be melted with a small quantity of water, with the addition of 4 oz. of camphor. When this last is fused, the mixture is taken from the fire; and while it is yet hot, a small quantity of plumbago is added to give it a leaden colour. When this is to be applied, the utensils must be heated to such a degree, that the hand can scarcely bear to touch them. In this state the composition must be rubbed on them, and afterwards wiped when the piece is dry. Those who prepare small shot, use black lead to polish or glaze it, by rolling or agitating them together with a quantity of plumbago. It is likewise used to make razor strops. When kneaded with clay, it makes excellent crucibles. One part of plumbago, three of argillaceous earth, and a small quantity of cow's dung very finely chopped, form an excellent lute for retorts; this lute is very refractory; and the glass will melt with the coverings changing its form. Aikin's Dict. Chaptal's Chem. vol. ii.

Pomet says, that plumbago was the sea-lead, *plumbum marinum*, of the ancients; who, he notes, took black-lead for a production of the sea, not a mineral, as it really is; but this is scarcely credible.

PLUMBAGO, in the *History of the Gems*, a word used by the Roman authors to express a blemish common to their worse kinds, and greatly debasing their value. It was a sort of blueish or blackish deadness in the stone, which mixed itself with the other colour, be that what it would, and rendered it dull and dead. The emerald was of all the gems the most subject to this fault; and in this case, its fine green colour was always rendered cloudy and blueish; and in some lights the stone appeared of a dusky greyish-blue,

with no green at all in it. The Bactrian emeralds, which were in great esteem with the ancients, were often subject to this imperfection; and those of Cyprus, taken out of the copper mines, though subject to many other imperfections, were usually quite free from this.

PLUMBAGO, in *Minerology*, a name given by many authors to a sort of fossil, having very much the appearance of a lead-ore, but not such in reality.

It is called also galena, blende, and mock-lead. It is usually of a plated texture, and dark blackish-blue colour, like the lead-ores; but on trial it yields no metal. See GALENA and BLENDE.

PLUMBARIA, in *Ancient Geography*, an island situated on the coast of Spain, near the promontory Dianium, according to Strabo.

PLUMBATÆ, among the *Ancients*, a kind of scourge, the thongs of which were armed with lead.

PLUMBATÆ likewise signified leaden balls, used by soldiers to annoy the enemy with; whence the soldiers were called *martibartuli*.

PLUMBERY, formed of *plumbum*, lead, the art of casting, preparing, and working lead; and of using it in buildings, &c. See LEAD.

The lead used in plumbery is furnished from the lead-works in large ingots, or blocks, called pigs of lead, ordinarily weighing about a hundred pounds a-piece.

As this metal melts very easily, it is easy to cast figures of it, of any kind, by running it into moulds of brass, clay, plaister, &c. But the chief article in plumbery is the sheets, and pipes of lead. They are these which make the basis of the plumber's work in building; the process of these, therefore, we shall give a description of.

Method of casting large Sheets of Lead.—The lead destined for this use is melted in a large cauldron or furnace, usually built with free-stone and earth, fortified on the outside with a mass of shards and plaister. At the bottom of it is a place sunk lower than the rest, in which is disposed an iron pot, or pan, to receive what may remain of the metal after the sheet is run. The furnace is so raised above the area of the floor, as that the iron pot just rests on it.

To use the furnace, they heat it with wood laid within it; that done, they throw in the lead at random with the burning coals, to melt.

Near the furnace is the table or mould, on which the lead is to be cast. This consists of large pieces of wood, well jointed, and bound with bars of iron at the ends. Around it runs a frame, consisting of a ledge or border of wood, two or three inches thick, and one or two high from the table, called the *sharps*. The ordinary width of the tables is from three to four feet; and their length from eighteen to twenty feet.

This table is covered with fine sand, prepared by moistening it with a watering pot, then working it with a stick; and at last, to render it smooth and even, beating it flat with a mallet, and planing it with a slip of brass, or wood.

Over the table is a strike or rake of wood, which bears and plays on the edges of the frame, by means of a notch cut in either end of it; and is so placed, as that between it and the sand is a space proportionable to the intended thickness of the sheet. The use of this strike is to drive the matter, while yet liquid, to the extremity of the mould.

At top of the table is a triangular iron peel or shovel, bearing, before, on the edge of the table itself, and behind, on a tressel somewhat lower than the table. Its use is in conveying the metal into the mould; and the design of its oblique disposition is, that it may by that means be able to retain the metal, and keep it from running off at the fore-side, where

where it has no ledge. Some of these peels are big enough to hold fifteen or sixteen hundred weight of lead, and even more.

Things being thus disposed, with a large iron ladle they take out the melted lead, coals and all, out of the furnace; and with this, mixed as it is, they fill the iron peel. When full, they take out the coals, and clear the lead with another iron spoon, pierced after the manner of a scummer.

This done, they hoist up the lower part of the peel by its handle; upon which the liquid matter running off, and spreading itself on the mould, the plumber conducts and drives it to the extremity of the table, by means of the strike, which the workman passes along the ledges, and thus renders the sheet of an equal thickness.

The sheets thus cast, there remains nothing but to edge them, *i. e.* to planish the edges on both sides, in order to render them smooth and straight.

Method of casting thin Sheets of Lead.—The table or mould here used is of a length or breadth at discretion, only ledged on one side. Instead of sand, they cover it with a piece of woollen stuff, nailed down at the two ends, to keep it tight; and over this they lay a very fine linnen cloth. The feet of the table are uneven, so that it does not stand horizontal, but moderately inclined.

Great regard is, in this process, had to the lead while melting, that it have the just degree of heat, so as it may run well, yet not burn the linen. This they judge of by a piece of paper; for if the paper take fire in the liquid lead, it is too hot; and if it be not shrunk and scorched a little, it is not hot enough.

Being then in its just degree, they have a strike, but different from that described in the former article; as serving both for peel and strike; both to contain and to conduct the liquid lead. It is, in effect, a wooden case without any bottom, only closed on three sides. It is pretty high behind, but the two sides, like two acute angles, still diminish to the tip, from the place where they are joined to the third or middle piece, where they are of the same height with it; *viz.* seven or eight inches high. The width of the middle makes that of the strike, which again makes that of the sheet to be cast.

The strike is placed at top of the table, which is before covered in that part, with a pasteboard, that serves as a bottom to the case, and prevents the linen from being burnt while the liquid is pouring in. The strike is so disposed on the table, as that the highest part looks to the lower end of the table, and the two sloping sides to the higher end.

The strike is now filled with lead, according to the quantity to be used; which done, two men, one at each side the table, let the strike descend down the table, or else draw it down with a velocity greater or less, as the sheet is to be more or less thick; the thickness of the sheet still depending on the promptitude with which the strike slides down the inclining mould.

The fine smooth sheets of lead, thus made, are sometimes used between the joints of large stones in great buildings, &c.

For the method of casting pipes, without folding, see PIPE. The folder which the plumbers use, is a mixture of two pounds of lead with one of tin. See **SOLDER**.

Plumber's work is commonly estimated by the pound or hundred weight; but the weight may be discovered by the measure of it, in the manner below stated. Sheet lead used in roofing, guttering, &c. is commonly between seven and twelve pounds weight to the square foot; but the following table shews by inspection the particular weight of a square foot for each of several thicknesses.

Thickness.	Pounds to a Square Foot.	Thickness.	Pounds to a Square Foot.
.10	5.899	.15	8.848
.11	6.489	.16	9.438
$\frac{1}{8}$	6.554	$\frac{1}{4}$	9.831
.12	7.078	.17	10.028
$\frac{1}{4}$	7.373	.18	10.618
.13	7.668	.19	11.207
.14	8.258	.2 = $\frac{1}{5}$	11.797
$\frac{1}{2}$	8.427	.21	12.387

In this table the thickness is set down in tenths and hundredths, &c. of an inch; and the annexed corresponding numbers are the weights in avoirdupois pounds, and thousandth parts of a pound. So the weight of a square foot of $\frac{1}{10}$ or $\frac{1}{100}$ of an inch thick, is 5 pounds and 899 thousandth parts of a pound; and the weight of a square foot to $\frac{1}{5}$ of an inch thickness is 6 pounds and $\frac{5}{1000}$ of a pound. Leaden pipe of an inch bore is commonly 13 or 14 pounds to the yard in length.

Examples.

1. How much weighs the lead which is 39 feet 6 inches long, and 3 feet 3 inches broad, at $8\frac{1}{2}$ lbs. to the square foot?

Decimals.	Duodecimals.
39.5	39 6
$3\frac{3}{4}$	3 3
-----	-----
118.5	118 6
9.875	9 10 6
-----	-----
128.375	128 4 6
$8\frac{1}{2}$	8 $\frac{1}{2}$
-----	-----
1027.000	1024
64.1875	64
-----	-----
1091.1875	2 $\frac{1}{2}$
-----	0 $\frac{3}{4}$

	Answer 1091 $\frac{1}{4}$ lbs.

2. What cost the covering and guttering of a roof with lead, at 18s. the cwt.; the length of the roof being 43 feet, and the breadth or girth over it 32 feet, the guttering 57 feet long, and two feet wide; the former 9.831 lbs., and the latter, 7.373 lbs. to the square foot? *Ans.* 115l. 9s. 1 $\frac{1}{2}$ d. *Hutton's Mensuration.*

PLUMBING, among *Miners*, a term used to express the using a mine dial, in order to know the exact place of the work where to sink down an air shaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it.

It is performed in this manner: a skilful person with an assistant, and with pen, ink, and paper, and a long line and a sun-dial, after his guess of the place above ground, descends into the adit or work, and there fastens one end of the line to some fixed thing in it; then the incited needle is let to rest, and the exact point where it rests is marked with a pen: he then goes on farther in the line still fastened, and at the next flexure of the adit he makes a mark on the line by a knot or otherwise; and then letting down the dial again, he there likewise notes down that point at which the needle stands in this second position. In this manner he proceeds from turning to turning, marking down the points,

and marking the line till he comes to the intended place ; this done, he ascends, and begins to work on the surface of the earth what he did in the adit, bringing the first knot in the line to such a place where the mark of the place of the needle will again answer its pointing, and continues this till he comes to the desired place above ground, which is certain to be perpendicularly over the part of the mine into which the air-shaft is to be sunk.

PLUMBUM. See **LEAD.**

PLUMBUM Corneum, called also *Saturnus corneus*, in *Chemistry*, is a metallic salt, formed by the precipitation of lead from its solution in nitrous acid with the marine acid, and all the neutral salts which contain it. It is thus called from its resemblance to the luna cornea. This salt may be made by other methods, and particularly by disengaging the volatile alkali from sal ammoniac by lead. In this way Mr. Margraaf makes the plumbum corneum, which he employs in the preparation of phosphorus. See **LEAD.**

PLUMBUM Ustum. See **Burnt LEAD.**

PLUME, a set or bunch of ostrich feathers, pulled out of the tail and wings, and made up to serve for ornament in funerals, &c.

PLUME, formed of *pluma*, feather, in *Falconry*, is the general colour or mixture of the feathers of a hawk, which shews her constitution.

When a hawk seizes her prey, and dismanacles it of its feathers, she is said to plume it.

PLUME, in *Botany*. See **PLUMULA.**

PLUME, La, in *Geography*, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Agen ; 7 miles S.S.W. of Agen. The place contains 1588, and the canton 6633 inhabitants, on a territory of $127\frac{1}{2}$ kilometres, in 10 communes.

PLUME Alum. See **ALUM.**

PLUMENAU, or **PLUMLAW**, in *Geography*, a town of Moravia, in the circle of Olmutz ; 4 miles W. of Prosnitz.

PLUMENTAAL, a town of Austria ; 4 miles W. of Zisterdorf.

PLUMERIA, in *Botany*, was so named by Tournefort, in honour of its discoverer, the celebrated Father Plumier. (See **PLUMIER**, CHARLES.)—Tourn. Inst. 659. t. 439. Linn. Gen. 117. Schreb. 164. Willd. Sp. Pl. v. 1. 1242. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 70. Juss. 145. Lamarek Illustr. t. 173.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Apocynæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, small, in five deep obtuse segments. *Cor.* of one petal, funnel-shaped ; tube long, gradually dilated upwards, naked at the mouth ; limb spreading, in five deep, ovate-oblong, oblique segments. *Stam.* Filaments five, awl-shaped, from the middle of the tube ; anthers converging. *Pist.* Germen superior, oblong, cloven ; styles scarcely any ; stigma double, pointed. *Peric.* Follicles two, long, pointed, tumid, bent downwards, drooping, each of one cell, and one valve. *Seeds* numerous, oblong, imbricated, winged with a membrane. *Receptacle* separate, cylindrical.

Ess. Ch. Corolla contorted, funnel-shaped : naked at the mouth. Follicles two, reflexed. Seeds with a membranous wing.

1. *P. rubra*. Red Plumeria. Linn. Sp. Pl. 306. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 279. (*P. flore roseo odoratissimo* ; Tourn. Inst. 659. Trew. Ehret. II. t. 41. Jafminum indicum ; Merian. Inf. Surinam. t. 8.)—Leaves ovate-oblong. Flower-stalks downy, even.—Native of Jamaica and Surinam, where it is cultivated on account of the

beauty and fragrance of its blossoms, which come out before the leaves. Merian says it is readily propagated, and grows rapidly. In our stoves it blossoms in July and August. The stem is thick and fleshy, forming a tall shrub, or small tree, in the course of a few months, and abounding with milky juice. Leaves deciduous, scattered, stalked, a span long, and one and a half or two inches wide, oblong, somewhat ovate or elliptical, pointed ; entire, smooth, with one thick rib, and many transverse veins, connected by a submarginal line. We find no traces of the two glands on the footstalks, mentioned by Linnæus, after Browne. The flowers are numerous, in a terminal cymose panicle, whose stalks, in all the specimens we have seen, are densely downy. The corolla expands near two inches, and is rose-coloured, with a yellow mouth.

2. *P. acuminata*. Sharp East Indian Plumeria. Ait. n. 2. (*Flos convolutus* ; Rumph. Amboin. v. 4. 85. t. 38.)—Leaves lanceolate, flat, taper-pointed. Flower-stalks smooth, even.—Native, as well as cultivated, in various parts of the East Indies, being much admired for its beautiful and fragrant white flowers. These, according to Rumphius, are sometimes candied with sugar. It was introduced at Kew, about 1790, by sir Joseph Banks, and flowers there from June to September. The habit of the plant is like the last, but the corolla is white with a yellow mouth ; the flower-stalks smooth ; and the leaves much more pointed. The tapering leaves, and less tumid or rugged flower-stalks, distinguish this from the following, which the flowers most nearly resemble.

3. *P. alba*. White West Indian Plumeria. Linn. Sp. Pl. 306. Willd. n. 2. Ait. n. 3. Jacq. Amer. 36. t. 174. f. 12. (*P. flore niveo, foliis longis angustis et acuminatis* ; Tourn. Inst. 659. Plum. Ic. 227. t. 231.)—Leaves lanceolate, revolute. Flower-stalks smooth, knotty above.—Native of the West Indies, on rocks by the sea side. Jacq. It flowers in our stoves in July and August, but is more rare than the first species. Nothing can exceed the fragrance of the large and elegant white flowers, whose inside, at the mouth of the tube, is yellow, as in the two preceding.

4. *P. obtusa*. Blunt-leaved Plumeria. Linn. Sp. Pl. 307. Willd. n. 3. Ait. n. 4. Aubl. Guian. v. 1. 259. (*P. flore niveo, foliis brevioribus obtusis* ; Tourn. Inst. 659. Plum. Ic. 228. t. 231. Catesb. Carolin. v. 2. t. 93.)—Leaves obovate, obtuse, with a short point.—Native of South America and the West Indies. It flowers in the stove in July, according to Mr. Aiton. Our specimen is from Aublet. The shape of the leaves, as above defined, is very different from any of the foregoing, with much more distant, less parallel, veins ; in which respect Plumier's plate is altogether unlike our plant. Our flower-stalks too are much more elongated, zig-zag, and copiously jointed. Aublet says it is as large as a pear-tree of the largest size. Burmann has very improperly confounded the synonyms of *P. rubra* with this, and Willdenow, like Linnæus, erroneously cites under it Rumphius's *Flos convolutus* ; see n. 2.

5. *P. pudica*. Virgin Plumeria. Jacq. Amer. 37. Willd. n. 4.—Leaves oblong, flat. Limb of the corolla closed.—Jacquin says he saw this plant cultivated in the gardens of Curaçao, where it was highly esteemed for its flowers, known there by the name of Douzellas, or virgins, because they are never expanded. Their colour is entirely yellow, and their scent, in the opinion of the author we quote, greatly excels every other *Plumeria*, and seemed superior to all the flowers with which he was acquainted. The shrub is five feet high, milky, with umbrageous, oblong, flat veiny leaves. Flowers lasting, in abundant succession, for two months,

months, their *corolla* always rolled up, like the *Achænia Malvarifcus*.

6. *P. cuneata*. Wedge-leaved Plumeria. Linn. fil. MSS. (*P. alba*; Aubl. Guian. v. 1. 259, excluding the synonyms.)—Leaves obovate, somewhat wedge-shaped, rounded, pointless; veins distant.—Cultivated at Cayenne, according to Aublet, who took it for the Linnæan *P. alba*. We have numerous *leaves* from his own herbarium, given by sir J. Banks to the younger Linnæus, who justly remarked that this must constitute a distinct species, though he had seen merely these separate *leaves*. Another specimen, apparently from the same herbarium, and likewise without *flowers*, is marked *P. laurifolia*; but it looks to us like a less blunt variety of Aublet's *obtusæ*.

The French name of this genus, *Frangipanier*, is rather remarkable. It is said to allude to its fragrance, *Frangipani* being a sort of perfume, so called in France from its inventor, an Italian, of the Frangipani family, so conspicuous in the Roman disturbances of the twelfth century.

PLUMERIA, in Gardening, contains plants of the succulent, flowering, exotic kind for the stove, of which the species cultivated are the red plumeria, or jasmine (*P. rubra*); the white plumeria (*P. alba*); the blunt-leaved plumeria (*P. obtusa*); and the close-flowered plumeria (*P. pudica*.)

Method of Culture—These plants are capable of being increased by seeds and cuttings of the young branches. The seeds should be procured from the native situation of the plants, and be sown in pots, filled with a light sandy compost, plunging them in a hot-bed, covered by glasses, or the bark-bed in the stove, when they readily vegetate; and when the plants have attained a few inches in growth, they should be removed into separate pots, of a small size, which must be plunged in beds of the same kind as above.

The cuttings should be made from the young branches, and after being laid in the stove or some other dry situation, to dispel their succulence, and heal over the wounds, be planted out during the summer months, in pots, filled with light dry mould, plunging them in the bark bed of the stove, giving occasional shade and very slight waterings, till they have stricken fresh root, and when they have become well rooted, they may be removed into separate pots, being managed as other stove exotics.

They afford much ornament and variety among collections of stove plants; especially the red sort; and when set out with other potted plants in the summer, have a delightful fragrance.

PLUMIER, CHARLES, in *Biography*, a French botanist and ecclesiastic, of the most respectable character, was born in 1646. He belonged to the religious order of Minims, and is described as of a simplicity of character becoming his monastic profession, if not invariably associated with it. To this he added the most enthusiastic love of botany, and a degree of accuracy and penetration rarely excelled in that science. He was sent, at the expence of the French king, on three different voyages to the West Indies; and was about to undertake a fourth, when he died of a pleurisy at Cadiz in 1704, aged 58.

His first publication is entitled *Description des Plantes de l'Amérique, avec leurs figures*, a splendid folio of above 100 pages, with 108 plates, which issued from the Louvre press, at the king's expence, in 1693. The text is French; the plates are outlines, drawn by Plumier himself, with a masterly hand. In the preface he relates, that he first imbibed a taste for botany at his convent of Trinità dei monti at Rome, from the lectures of Father Sergeant, a French monk, and of de Onuphrius, a Roman physician. By this taste he was insensibly diverted from the mathematics, which

have always been much studied in that convent, even to our own times. Being ordered to his native country, he obtained the permission of his superiors to botanize on the shores of Provence, and the mountains of the Alps. Here he meditated a general *Pinax*, or System of Botany, with figures, of which he had actually drawn a considerable number, when he found at Marseilles an opportunity of sailing to America. Begon, intendant of the French navy, furthered his views, and procured for him the patronage and support of government; by which action alone, if by nothing else, the intendant may be said to have merited his own botanical honours. (See BEGONIA.) Of the plates of this book, 50 are devoted to the fern tribe, and contain many curious species, previously unknown to botanists. The rest of the engravings consist of many species of *Piper*, *Arum*, and *Passiflora*, with other climbing plants. Their parts of fructification are not critically detailed; but that defect was supplied in the author's *Nova Plantarum Americanarum Genera*, a thin quarto, published in 1703, after his third voyage. In this book 106 new genera are established, and illustrated with plates. The manner and principles of Tournefort are adopted throughout. In his nomenclature, Plumier is profuse in honouring botanists, as well as in adopting the most uncouth words of barbarous origin; scarcely constructing one original name, of Greek or Latin derivation, except perhaps *Saururus*, a genus now sunk in the more ancient *Piper*. Haller justly complains, that Plumier falls into the imperfections of Tournefort, with respect to his superficial mode of considering the parts of the flower, and his inattention to number in their description. He hints also that some of the delineations have a doubtful or suspicious aspect. That some of these figures are erroneous in parts, cannot be denied; as the stamens of *Fuchsia*, the stigmas of *Plukenetia*, and the whole flower of *Matthiola*; besides abundance of slight negligences or inaccuracies; but we must not try the performances of one of the fathers of scientific botany, by the test of our present advanced knowledge.

The Ferns of Plumier's first publication were reprinted with a great number of additional figures of the same tribe, very finely executed, in another splendid folio, containing 172 plates, with Latin as well as French descriptions. In the preface he investigates all that had been said relative to the flowers of these plants; and though he attributes to Tournefort a sentiment of Pliny's, he proves himself sufficiently conversant with botanical writers. To give the more consequence to his favourite pursuit, he very commendably enlarges on the benefits which medicine may derive from the study of the vegetable world: but as Rousseau's Swiss herbalist died of a pleurisy, whilst employed in gathering a sovereign Alpine remedy for that disorder; so it is not improbable that Plumier was extolling the *Polytrichum*, see his preface p. 2, as "un antipleuritique des plus affurez," when he himself fell a victim to the very same disorder; leaving his half-printed book to be his monument. So much easier is it for an ardent botanist to catch a pleurisy, we write from the conviction of experience, than to cure one!

The above works contained but a small part of the productions of Plumier's pencil. Vast treasures of his drawings, in outline, have remained in the French libraries, for the most part unpublished. The late earl of Bute obtained copies of a great number of these, which after his lordship's death passed into the hands of sir Joseph Banks. Boerhaave had previously procured copies of above 500, done by the accurate Aubriet, under Vaillant's inspection, which were afterwards, in great part at least, published by John Burmann

mann at Amsterdam, between the years 1755 and 1760. These plates are executed with tolerable, but by no means infallible, accuracy, being far inferior in neatness and correctness to what Plumier himself published. The well-meaning editor has overloaded the book with descriptions of his own, necessarily made from the figures, and therefore entirely superfluous. They are indeed not unfrequently founded in misapprehension; nor has he been very happy in the adaptation of his materials to Linnæan names and principles. He ought rather, as Lamarck observes, to have given Plumier's materials without alteration or addition. A careful reader may, nevertheless, avoid being misled; as the original names and definitions of the author are subjoined. It is a pity that nothing is preserved of the native country, history, properties or colours of each plant.

Father Plumier wrote, in the *Journal des Sçavans* for 1694, and elsewhere, on Cochineal, and some subjects connected therewith; proving that valuable article of commerce to be an animal, and not any thing of a vegetable nature. His opinion was, in every essential point, confirmed, as well as more precisely illustrated and established, by Richter, in his rare little treatise *de Cochinilla*, published at Leipzig in 1701.

Our author left no herbarium of his own, his collection of dried plants having been lost at sea; but he had, on various occasions, communicated dried specimens to Tournefort; and these still remain, with his hand-writing annexed, in the collections at Paris. Lister, who visited Plumier in his cell at the convent of Minims in that city, speaks of his obliging and communicative manners, and of his "designs and paintings of plants, birds, fishes, and insects of the West Indies, all done by himself very accurately." It appears that, notwithstanding the royal favour, he was obliged to solicit repeatedly, and mostly in vain, for the publication of his drawings at the king's printing-press; so imperfect is government patronage for science on all occasions, and in all countries! See Lister's Journey to Paris. Plumier's Works. Haller Bibl. Bot.

PLUMMER'S ETHIOPS. This medicine is composed of the sulphur auratum antimonii and calomel, commonly in equal parts, *e. gr.* of each three drams; but this may be varied occasionally, according to the physician's discretion. These two powders must be well levigated together, by which the bright red colour of the sulphur is changed into a dusky brown; afterwards, add two drams of the extract of liquorice; and the mass, with a sufficient quantity of the mucilage of gum arabic, may be made into pills. We refer to the Medical Essays of Edinburgh for the dose, regimen to be observed, and effects of this medicine; as also for the manner of preparing the sulphur of antimony according to Angelus Sala, which is said to be preferable to the common method. See Med. Ess. Edinb. abridg. vol. i. p. 205. vol. ii. p. 455.

This medicine has been found greatly beneficial in cutaneous eruptions, and is said to have completed a cure after salivation has failed, in venereal infections, and in gleet remaining after the cure of a gonorrhœa. It operates by carrying off the excrements of distempers by insensible perspiration or sweat. It has also been found successful in obstinate glandular swellings; two or three pills of an ordinary size may be taken night and morning, the patient keeping moderately warm, and drinking after each dose a draught of the decoction of the woods, or of sarsaparilla.

PLUMMET, *Plumb-rule*, or *Plumb-line*, an instrument used by masons, carpenters, &c. to draw perpendiculars; in order to judge whether walls, &c. be upright, planes horizontal, and the like.

It is thus called from a piece of lead, *plumbum*, flattened to the end of a thread or chord, which usually constitutes this instrument.

Sometimes the string descends along a ruler of wood or metal raised perpendicularly on another; in which case it becomes a level.

At sea a plummet is used by the pilot to sound the depth of the water.

PLUMOSE ANTENNÆ, in *Natural History*, a term used to express the antennæ, or horns of certain moths and butterflies, which are formed in the manner of feathers, being composed of a stem and fibres issuing on each side from it: these are jointed and moveable any way; and even the small fibres, at their sides, are jointed at their bottom, and are moveable, but they move all together. See FEELERS.

PLUMSTEAD, in *Geography*, a post-town of Pennsylvania, situated on the west side of Delaware river; 36 miles N. of Philadelphia.

PLUMULA, in *Botany* and *Vegetable Physiology*, so called from its resemblance to a little feather, is the expanding embryo of a seed just sprouting, which soon becomes a tuft of young leaves, elevated by the protruding stem. See EMBRYO and COTYLEDONES.

PLUNDER, in *Sea Language*, a name given to the effects of the officers or crew of a prize, which are pillaged by the captors.

PLUNGE, in the *Manège*. See ESTRAPADE.

PLUNGER, in *Mechanics*, a solid brass cylinder used as a forcer in forcing pumps.

PLUNGER is also a large vessel, intended to act as a counter-poise for raising the water in a lock, in some of the schemes for saving water. See CANAL.

PLUNOS, in *Ancient Geography*, a port of Lybia, at the extremity of the country of the Adymachides; mentioned by Lycophron and Herodotus.

PLUQUET, FRANCIS ANDREW, in *Biography*, a French abbé of some celebrity in the 18th century, was born at Bayeux, in Normandy, in 1716. He was educated for the church, and obtained some preferment in it: after this, he was nominated to fill the chair of professor of history in the university of Paris. By his lectures he acquired a considerable share of reputation, the claim to which he ably supported by several useful and well-written works. He died in 1790, at the age of 74, having maintained through life the character of a truly virtuous good man. His principal publications are, "An Examination of the Doctrine of Fatalism," in 3 vols. 12mo.; "A Dictionary of Heresies," in 2 vols. 8vo.; "A Treatise on Sociability," in opposition to the system of Hobbes, and to prove that man is disposed to benevolence and religion; "The Classical Books of the Chinese Empire," in 4 vols. 12mo., translated from the collection of father Noel; and "A philosophical and political Treatise on Luxury," in 2 vols. 12mo.

PLURAL, **PLURALIS**, in *Grammar*, a particular inflexion of nouns and verbs, whereby they come to express a plurality or number of things.

The Latins, English, &c. have only two numbers, *singular* and *plural*; the Greeks and Hebrews have three, *singular*, *dual*, and *plural*.

In Latin, &c. both nouns and verbs have usually distinct terminations to their different numbers; in English, nouns substantives usually become plural by the addition of an *s* or *es* to the singular.

Nouns adjective are the same in both numbers; and in verbs, the number is distinguished by that of the pronouns.

PLURALITY, **PLURALITAS**, a discrete quantity, consisting of two, or a greater number.

A plurality

A *plurality of worlds* is a thing which Mr. Huygens has endeavoured to prove in his *Cosmotheoros*. And the same is likewise contended for in a very pretty treatise of M. Fontenelle under that title.

See the chief argument for a plurality of worlds under MOON, PLANET, and EARTH.

The greatest absurdity in the pagan theology is the *plurality of gods*.

PLURALITY of *Benefices*, or *Living*s, is where the same clerk is possessed of two or more spiritual preferments, with cure of souls. See BENEFICE.

Plurality of benefices is a thing too much tolerated in the church, but never approved of.

It was the smallness of some benefices that first gave occasion to pluralities; for an ecclesiastic, not being able to subsist on a single one, was allowed to hold two; and at length the number increased without bounds.

The abuse was endeavoured to be remedied at the council of Lateran, under Alexander III. and Innocent III., in the year 1215, when the holding more than one benefice was expressly forbid by a canon, under the penalty of deprivation: but the same canon granting the pope a power to dispense with it in favour of persons of distinguished merit, there were so many found a title to this merit, that the prohibition became useless.

Pluralities were also restrained by statute 21 Hen. VIII. cap. 13, which enacts, that if any person, having one benefice with cure of souls, of the yearly value of 8*l.* or above, (in the king's books,) accept any other with cure of souls, the first benefice shall be adjudged in law to be void, &c., though the same statute provides for dispensation in certain cases. For other provisions of a later date, see CHAPLAIN and CURATE.

In order to procure a dispensation, the presentee must obtain of the bishop, in whose diocese the livings are, two certificates of the values in the king's books, and the reputed values and distance of such livings; one certificate for the archbishop, and the other for the lord chancellor. And if the livings lie in two dioceses, then two certificates, of the same kind, are to be obtained from each bishop. He must also exhibit to the archbishop his presentation to the second living; and bring with him two papers of testimonials from the neighbouring clergy, concerning his behaviour and conversation, one for the archbishop, and the other for the lord chancellor; and he must also exhibit to the archbishop his letters of orders of deacon and priest, and a certificate of his having taken the degree of master of arts at the least, in one of the universities of this realm, under the hand of the register of such university. And in case he be no doctor or bachelor of divinity, nor doctor of law, nor bachelor of canon law, he is to procure a qualification of a chaplain, which is to be duly registered in the faculty office, in order to be tendered to the archbishop, according to the statute. And if he hath taken any of the aforesaid degrees, which the statute allows as qualifications, he is to procure a certificate thereof as already mentioned, and to exhibit the same to the archbishop; after which his dispensation is made out at the faculty office, where he gives security according to the direction of the canon. Afterwards he must repair to the lord chancellor, for confirmation under the broad seal; and then he is to apply to the bishop of the diocese where the living lies, for his admission and institution. By 48 Geo. III. c. 149, for every skin, or paper, or parchment, &c. on which any dispensation to hold two ecclesiastical dignities or benefices, or a dignity and a benefice, shall be engrossed or written, there shall be paid a stamp duty of 3*0l.*, when either of them shall be

above the yearly value of 10*l.* in the king's books; and in all other cases 20*l.*

We have also a regulation in regard to pluralities; but it is often dispensed with; for, by the faculty of dispensation, a pluralist is required, in that benefice from which he shall happen to be most absent, to preach thirteen sermons every year, and to exercise hospitality for two months yearly.

In Germany the pope grants dispensations for possessing a plurality of benefices, on pretence that the ecclesiastical princes there need large revenues to bear up against the Protestant princes.

PLURIES, in *Law*, a writ that issues in the third place after two former writs have been disobeyed: for first goes out the original writ or *capias*, which, if it has no effect, then issues the *alias*; and if that also fails, then the *pluries*. Old. Nat. Br. 33.

It is used in proceedings to outlawry, and in great diversity of cases. Tabl. Reg. Writs.

PLURS, in *Geography*. See PLEURS.

PLUS, in *Algebra*, a term commonly used for *majus*, of *magis*, *more*; denoted by the character +.

Thus $4 + 10 = 14$, is read, four, plus, or more, 10, is equal to 14.

PLUSH, in *Commerce*, &c., a kind of stuff having a sort of velvet nap or shag on one side; composed regularly of a woof of a single woollen thread, and a double warp, the one wool, of two threads twisted, the other goats' or camels' hair; though there are also some plushes entirely worsted, and others composed wholly of hair.

Plush is manufactured, like velvet, on a loom with three treadles. Two of these separate and depress the woollen-warp, and the third raises the hair-warp, upon which the workman throwing the shuttle, passes the woof between the woollen and hair-warp; and afterwards laying a brass broach, or needle, under that of the hair, he cuts it thereon with a knife destined for that use, conducting the knife on the broach, which is made a little hollow, all its length; and thus gives the surface of the plush an appearance of velvet.

Some ascribe the invention of plush to the English; others say it was first made in Holland, and particularly at Haerlem. Be this as it will, it is certain the French are the people who make the most of it; there being several very considerable plush manufactures at Amiens, Abbeville, and Compeigne.

There are other kinds of plush, all of silk; some of which have a pretty long knap on one side, and some on both.

PLUSH, among *Botanists*, is a name given to the middle of roses, anemones, &c., called also *thrum* or *thrummy heads*; by others, *hairy heads*, *buttons*, *bafs*, *tuft*, or *wort*.

This is properly the *stamina* of the flower.

PLUTARCH, in *Biography*, an eminent biographer, was born at Chæronea in Bœotia, of a family that had long filled the offices of magistracy in that city. The time of his birth is not exactly ascertained, but it was probably about the commencement of the reign of Nero. He studied under a philosopher of the name of Ammonius, whose particular sect is not known. After he had completed the usual course of academical education, he travelled for improvement; and it is said that he visited Egypt: there is, however, no other evidence of this fact than that he wrote a treatise on Isis and Osiris. His attachment to study did not prevent him from engaging in public business. While he was a very young man, he went on a deputation to the Roman proconsul; and it was probably in some public capacity that he first visited Rome, and other parts of Italy;

for

for he says, he had not leisure at that time to learn the Latin language, on account of the number of commissions with which he was charged, and the numbers who resorted to him in order to be instructed in philosophy. He either revisited Rome, or made it his continued abode for a considerable time, since we find him in reputation there during the reign of Trajan, who is supposed to have been one of his auditors. That same emperor is said to have raised Plutarch to the consular dignity: this, however, was probably only a titular honour. He finally retired to his native place, in which he fixed his residence, giving this as a reason, that being born in a little city, he would not make it less by deserting it. Here he was chosen to the office of archon, or chief magistrate, and was afterwards admitted into the college of priests of the Delphic Apollo. He is thought to have died about the year 120. He was married, and had several children. Two sons survived him, *viz.* Plutarch and Lamprias; the latter probably imitated his father in his studies, as he drew up a catalogue of his works, and is supposed to have collected his apophthegms. He had a nephew, Sextus, who was preceptor in the Greek language to the emperor Marcus Antoninus. The name of Plutarch is popularly known by his "Lives" of illustrious men, one of the most interesting remains of ancient literature, and to which, in our biographical articles, we have had frequent recourse. A vein of pure morality runs through them, with a spirit of piety, occasionally deviating into superstition. From the list of his writings it appears that several of his biographies are lost. Plutarch's moral treatises are numerous and valuable; the author does not excel in depth and sagacity, but his sentiments are commonly marked with good sense and candour. In kindness of heart and humanity few philosophers have surpassed him. It appears from his son's catalogue, that more of his works of the moral and critical class have been lost than preserved. Of the complete works of Plutarch, the best editions are those of Maufac and of Reiske. There are numerous editions of the Lives, and other detached works, translated into various languages. In our own language we have a great number of different editions.

Though no dictionaries or biographical accounts in our country, or in France, seem to have taken notice of his knowledge and love of music, or of his writings on the subject, M. Burette, in the 8th vol. 4to., and 11th abridg. of the Memoirs of the Acad. des Inscriptions et Belles Lettres, in 1726, took up the subject of ancient Greek music, and, with a true critical spirit, laid open all its arcanæ, after a long study of modern music, and the Greek writers who have treated of it *ex professo*, or incidentally; letting us know nearly all that is to be known with certainty of this mysterious subject.

After denying to the ancients, in the most formal terms, the knowledge of counterpoint, he proceeds to the examination of Plutarch's "Dialogue on Music," first removing all doubt of its having been written by him, which had been disputed, and then proceeds to a close, and, in general, faithful translation, which he gives opposite to the original text; and proves from that work itself, that the ancients were perfectly ignorant of composition, or music in parts. And what gives greater force to this proof is, that Plutarch was thoroughly versed in the subject which he treats. He writes of the nature of sound, so far as was then known; of its generation and proportions; of the genera, intervals, modes, rhythm, melopœia; explains the musical technica of the Greeks, (not the notation,) but neither quotes nor mentions any practical musician, except Aristoxenus. Of poet musicians, from Homer to the time of Alexander

the Great, he makes honourable mention, but of none after.

He speaks frequently of music having been corrupted by the theatre, particularly in his "Dialogue," where he says, "If we look back into remote antiquity, we shall find that the Greeks were unacquainted with theatrical music. The only use they made of this art was in praising the gods, and educating youth. The idea of a theatre had not then entered their thoughts, and all their music was dedicated to sacrifices, and to other religious ceremonies, in which they sung hymns in honour of the gods, and canticles in praise of great and good men."

It should be remembered here, that Plutarch was a priest of Apollo; and, moreover, that what he, Plato, and Aristoxenus say, concerning the injuries which music had received from the theatre, favours very much of cant and prejudice. Athenæus, on the contrary, tells us, that notwithstanding the complaints of Aristoxenus against theatrical corruption, others were of opinion, that music derived its principal improvements in Greece from the theatre; and it seems natural, that the hope of applause, and the fear of censure, should operate more powerfully on the industry and faculties of a composer or performer, than the idea of private praise or blame. And, if we may judge of ancient times by the present, the theatre seems the place to develop all the powers of music, and to expand the talents of its professors: for it is at the musical theatre, the modern temple of Apollo and the muses, that perfection of various kinds is more frequently found than any where else. But old things do get violently praised, particularly music, after it ceases to give pleasure, or even to be heard; and old people exclusively praise what pleased them in their youth, without making allowance for their own want of judgment and experience at that time, which, perhaps, joined to the disposition of youth to be easily pleased, occasioned their former delight.

It is natural to suppose as Greek music, like other arts, and other things, must have had its infancy, maturity, and decrepitude; that in second childhood, as its effects were more feeble, its pursuits would be more trivial than before its decline. Few great actions were achieved by the Greeks after their total subjection. However, they cultivated music under the Roman emperors, under their own, and are still delighted with it under the Turkish government; but their music is now so far from being the standard of excellence to the rest of the world, that none but themselves are pleased with it.

Plutarch treats the subject of music in a manner less dogmatical than historical. The two principal branches of the art, upon which he lays the most stress, are the harmonical and rhythmical; that is, *tone*, or melody, and *time*.

In M. Burette's notes, he gives a biographical account of all the ancient poets and musicians mentioned in the course of the Dialogue; which saves his readers much trouble in seeking them, dispersed as they are through all literature; and greatly enlivens the translation of many parts of the treatise, that are now either unintelligible or useless.

Upon the whole, however, there is more to be learned from this Dialogue, concerning the history, and indeed practice, of ancient music, thus illustrated and explained, than in Meibomius, Ptolemy, and all the philosophers and mathematicians, who only treat of the monochord, ratios, and harmonics, without giving us a single passage of ancient music, or telling us what it was in practice.

PLUTEI, in the Roman *Art of War*, were engines contrived for the defence of soldiers, consisting of the same materials

materials with the vineæ, but of a different figure; being shaped like an arched sort of waggon, and having three wheels, so conveniently placed, that the machines would move either way with equal ease.

PLUTO, in *Mythology*, the son of Saturn and Rhea, and sovereign of the empire of darkness. Statius calls him the black Jupiter; and he is represented by the poets as seated on a throne, holding his sceptre in his hand, which had two points by way of distinguishing it from Neptune's trident, which had three, with a veil over his head, which, as well as his complexion, should be dark and terrible. He is sometimes called by the name of Dis.

The fable of Pluto's having had hell or the empire of darkness assigned him for his lot is thus explained by *Diodorus Siculus*. He says, that it arose from his being the first who founded the custom of burying the dead, of transferring them into sepulchres, and of bestowing other services upon them, which before him had been neglected. But *Banier*, not thinking it probable that duties so natural would have been neglected till the time of Pluto, is of opinion, that he was reckoned the king of hell, because he lived in a very lone country in respect of Greece, where Jupiter had fixed his empire. This country was the extremity of Spain, where he busily employed himself in working at the gold and silver mines, which were very common near Cadiz, where he fixed his residence. Spain was anciently reckoned a country abounding with rich mines; and near Tartesus, at the mouth of the river Betis, it is said there was a mountain of silver: and from this name of the island Tartesus, Tartarus is supposed to have been derived. This circumstance induced Pluto to fix his residence in this island, and hence he obtained the name of Pluto, the god of riches, and has been sometimes confounded with Plutus. Besides, Pluto's kingdom was not only low in respect of situation compared with Greece, but as Pluto employed labourers in the mines, who dug into the bowels of the earth, and penetrated, as it were, to the gloomy mansions of the manes, *adn.*, or hell, in search of hidden treasures, he was reckoned king of the dead. Besides, the ocean, on the coast of which he reigned, was accounted a place over-spread with darkness, and this, as *Banier* imagines, was the foundation of all the fables that were invented concerning Pluto and his realms of darkness. Tartarus he supposes to have been derived from Tartesus near Cadiz, and the river Lethe from Guadelethe, which runs over-against that city, and the lake Avernus from the word Abarona, importing *at the extremities*, a name given to that lake, which is near the ocean; accordingly Pluto was particularly worshipped at Cadiz, under the name of Death, as *Philostratus* has observed; of which there can be no doubt, since the Phœnicians, whose language was established at Cadiz with the colonies planted there by Hercules, called Pluto *Muth*, their name for Death. We might also add, that all the names given to him, or the countries where he was worshipped, have a relation to this title, "god of the dead." For the rape of Proserpine by Pluto, see *PROSERPINE*.

PLUTUS, the god of riches, reckoned amongst the number of infernal deities, because riches are derived from the bowels of the earth. *Hesiod* makes him to be a descendant of the Ceres and Jasion in the isle of Crete, probably because these two persons applied themselves to agriculture, which is the means of obtaining the most substantial riches. Plutus had a statue at Athens, placed in the temple of Minerva, where the public treasures were deposited; at Thebes, in the temple of Fortune, this goddess holds Plutus in her arms as an infant, nourished by her;

and at Athens, Plutus is in the arms of the statue of Peace, as the symbol of riches, which give peace.

This Plutus, having been observed to dispense his favours very unequally, was therefore represented as blind: and *Aristophanes* in his "Plutus" adds, that he was lame, because whenever he had a mind to enrich the good, he came to them very slowly; and when it was his intention to favour them, he was very clear-sighted, and said to have good eyes. *Pindar*, *Aristophanes*, and *Lucian* inform us, that Plutus was a daftardly god, on which circumstance *Erasmus* has founded one of his proverbs; but Plutus vindicates himself from that imputation, in the comedy above cited, and says, that as thieves and robbers never could catch him, that is, never could acquire great riches, they hence constructed his precaution and foresight to be cowardice. *St. Jerom*, followed by several ecclesiastical writers, alleges that the Syriac or Chaldaic word "Mammona" was the same with the Plutus of the Greeks.

PLUVIAL, **PLUVIALE**, anciently signified a hood or cloak; which ecclesiastics, chiefly religious, wore in the country, to shelter themselves from the rain; by the Latins called *pluvialis lacerna*.

The word is now used, in the Romish church, for a large hood worn by the chanter and subdeacon at mass and vespers, &c. It covers the whole man, and is fixed before with two clasps.

PLUVIALIS, in *Ornithology*. See **PLOVER**.

PLUVIALIS Major, a name given by some authors to the limosa, a bird in some respects resembling our red shank, but larger and longer legged.

This bird is also called the *glottis*. See **SCOLOPAX Glottis**.

PLUVIALIS Levis, a name given by many to the common green wood-pecker, the *picus viridis* of authors, called also in English the *rain-fowl*, from an observation of its always being most clamorous when rain is coming on. See **PICUS Viridis**. See also **CUCULUS Pluvialis**.

PLUVIGNER, in *Geography*, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of L'Orient; 14 miles E. of L'Orient. The place contains 4800, and the canton 12,476 inhabitants, on a territory of 252½ kilometres, in seven communes.

PLUVIUS, in *Antiquity*, an attribute of Jupiter; implying him the author of rain; *q. d.* he that sends rain. Among the basso relievos of the Antonine column, in the place where the miracle of the thundering legion is represented, we see a flying man in the air, his arms spread out, and with a very long beard, which seems to dissolve into rain. The learned take this to be a representation of Jupiter Pluvius. The Athenians worshipped him under this name, as we learn from *Pausanias* in Attic.

PLYERS, in *Fortification*, denote a kind of balance used in raising or letting down a draw-bridge. They consist of two timber levers, about twice the length of the bridge they lift, joined together by other timbers framed in the form of a St. Andrew's cross, which serves as a counterpoise. They are supported by two upright jambs, on which they swing; and the bridge is raised or let down by means of chains joining the ends of the plyers and bridge.

PLYING, or **PLYING to Windward**, in *Seaman'ship*, the act of making, or endeavouring to make, a progress against the direction of the wind. Hence, a ship that advances well in her course in this manner of sailing, is said to ply well, or be a good plying. See **BEATING**, in *Navigation*.

Plying is also used by ferrymen to denote their waiting for a fare.

PLYMOUTH.

PLYMOUTH, in *Geography*, a town having separate jurisdiction, in the hundred of Roborough, at the western extremity of Devonshire, is 218 miles W. S. W. from London. It is situated at the head of a capacious haven, formed by the conflux of the rivers Tamar and Plym with the sea, and is probably the largest corporate town in the county, as well as one of the most important maritime places in England. Within a circuit of two miles, including its appendages of Stonehouse and Dock, there is a population of between 60,000 and 70,000 people, exclusive of seamen and foldiers. Plymouth is of considerable antiquity, and was called, in the time of the Saxons, Tameorwerth: after the Conquest it acquired the name of South-Town, or Sutton; and in the reign of Edward I. of Sutton-Prior, and Sutton-Valletort, the north part of the town being situated on the lands of the prior of Plympton, and the south part on the estate of the Valletorts. These names were relinquished in the reign of Henry VI., for the more appropriate appellation of Plym-mouth. In the reign of Edward III. the increasing consequence of the town rendered it an object of jealousy to the French, who landed here, and endeavoured to destroy it by fire; but were repulsed, with the loss of 500 men, by Hugh Courtenay, earl of Devonshire, under whose command the surrounding gentry and their vassals had associated with much celerity. In the sixth year of Henry IV. the French were more successful, when they landed near that part now called Briton-side, and burnt upwards of 600 houses; but failing in their attempts against the castle and higher part of the town, they retired to their ships, and proceeded to Dartmouth, where their commander, De Castell, and several hundred men, were made prisoners. From this time till the reign of Henry VI., the town dwindled into a mere fishing village; when it was rebuilt and improved by the prior of Plympton, who, by granting certain privileges, occasioned a considerable increase of inhabitants, and effected the revival of trade and enterprise. In the 18th year of Henry VI. it was incorporated as a borough, and on the dissolution of monasteries, in the reign of Henry VIII., the entire lordship of the borough, together with the patronage of the religious establishments within or near the town, were given to the mayor and commonalty, and these advantages they still retain. In the reign of queen Elizabeth, through the means of sir Francis Drake, various privileges were granted to the town, and at the private expence of the same gallant admiral, a stream of water was conveyed to it from some springs on Dartmoor, by a winding channel of twenty-four miles in length. In the year 1579, Plymouth was visited by a dreadful plague, supposed to have been introduced with some cotton-wool, landed from a Smyrna ship, without first being properly aired. Upwards of 600 persons fell victims to its ravages; and so general was the fear of its spreading, that the annual election for mayor was held in the open air, on Cat-down, some distance from the town. In 1581 the plague again broke out, and continued several months; and many of the inhabitants became victims to its violence. At the period of the expected invasion by the Spanish Armada, in 1588, a British fleet of 120 sail was assembled in Plymouth Sound, under the command of lord Howard, and the admirals sir Francis Drake and sir John Hawkins. This fleet failed for Torbay to join the Exeter ships; and soon afterwards the grand Spanish armada, which papal arrogance had pronounced invincible, appeared in the form of a crescent, and lay to off the harbour of Plymouth; but proceeding to the eastward, it was assailed by the British fleet, and a destruction thus commenced was completed by a violent storm, which utterly

frustrated the expedition. In 1595, the landing of the Spaniards in Cornwall, (for which see PENZANCE,) threw the inhabitants of Plymouth into much alarm, and caused the adoption of various precautions to ensure their safety. From this period till 1625, nothing material occurred, when Charles I. with his whole court, 120 ships, and 6000 troops, came from Portsmouth, and remained here ten days, sumptuously entertained by the mayor and corporation. In the following year, Plymouth was a third time infested by a plague, which raged with incredible fury, till nearly 2000 persons were destroyed. About 1637, in consequence of a petition to that effect from the mayor and commonalty, the town was divided into two parishes, and in 1640, an act was obtained for the erection of a new church; but the civil wars, which soon after ensued, occasioned the suspension of this latter design. At the breaking out of the civil war, Plymouth very early declared in favour of the parliament, and the year 1643 forms a memorable era in the annals of its history, from the spirited resistance made by the inhabitants against the forces of prince Maurice, who besieged it from September till the close of the year without success. What the citizens wanted in means of defence, was made up to them in enthusiasm, and they held out till the parliamentary forces, under the earl of Essex, approached to their relief. On the surrounding eminences are still to be traced the remains of various works, constructed both for the defence and reduction of the town. The different attempts of the royalists, under the king in person, and his general, sir Richard Grenville, successively proved abortive, and they were finally compelled to raise the siege, and entirely withdraw their forces. In the year 1683 the charter of the town was surrendered to the king, on the requisition of judge Jefferies, and a new one granted at an expence of 417*l.* 19*s.* This vested the power in ten aldermen and twelve assistants only, and continued in force till the latter end of the year 1697, when the old charter was restored, though not before upwards of 600*l.* had been ineffectually expended.

Various fortifications have been at different times erected for the security of Plymouth, and it is now in a state of respectable and formidable defence. Several smaller block-houses and forts were demolished on the building of the citadel on their site, in the time of Charles II., in 1670. This strong fortress consists of three regular, and two irregular bastions; and the curtains of the regular bastions are further strengthened by two ravelins and horn-works. On the east, north, and west sides is a deep ditch, counter-scarp, and covered way, palisaded. In the time of war the parapets are mounted with a great number of heavy ordnance, and the garrison consists of a regiment of militia. A lieutenant-governor, and other officers, reside here. The view from the ramparts is exceedingly beautiful, and comprehends a great variety of interesting objects. There is a lower fort, connected with the citadel, and chiefly intended for the defence of the sound. Besides these works, several batteries and block-houses are raised on different points of the harbour; on mount Batten, Staddon-heights, and at Maker; but its chief security is St. Nicholas isle and its formidable batteries. This island rises nearly in the centre of the sound, between the Plymouth shore and mount Edgcomb. Between the latter and the island is a ridge of rocks, great part of which is visible at low water, and renders the entrance into the sound, or harbour, difficult and dangerous.

The Victualling office, under the eastern walls of the citadel, is an extensive range of buildings, where the ovens for supplying

PLYMOUTH.

supplying the navy with bread, and the ingenuity exercised in the baking and preparations, present interesting objects: though there are but two bakehouses, each containing four ovens, yet they are heated eight times a day, and in the course of that time bake a sufficient quantity of bread for 16,000 men. The granaries are large and well constructed; and the whole process of converting the grain into bread is simple and ingenious.

The town itself has very few claims either to elegance or neatness; the streets are in general ill constructed, irregular, and badly paved, but a better taste characterises the improvements which are taking place. Amongst the public buildings the most ancient is the parish church, which consists of a nave, side aisles, and chancels, with a tower at the west end, ornamented with pinnacles. This structure contains several curious and ancient monuments. The precise period of its erection is not known, but it is mentioned in a general survey in the year 1291. The tower is of more recent date, having been built, in 1440, by Thomas Yogge, a merchant of the town. The other church, begun in 1646, is consecrated to the memory of Charles I., and called Charles's church. Sectarists are numerous, and here are various meeting houses, chapels, and a synagogue for Jews. The Guildhall, lately rebuilt on the site of a more ancient one, is a very indifferent edifice. It contains a few portraits of some of the English sovereigns and other illustrious personages. Adjoining the guildhall, and connected with it, are the public prisons of the town; they consist of a room for debtors, and several cells for prisoners, all very small and inconvenient. There are twenty-one charitable institutions in Plymouth, some of them established and supported by the town, others by voluntary contribution, and the rest from the annual income of donations by individuals. Of the former are the workhouse, which is a very useful and well regulated institution; St. Andrew's alms-houses, in which twelve widows are permitted to live gratis, with a small weekly allowance; and the workhouse alms-houses, of a similar nature with the last. Those supported by voluntary contribution are the Public Dispensary, Household of Faith, Female Asylum, Grey and Yellow School, School of Industry, Public School, on the new plan of instruction designed by Dr. Bell and Mr. Lancaster; Misericordia, Lying-in-Charity, and Merchants' Hospital, for maimed and disabled seamen, and the widows and orphans of such as are killed, slain, or drowned in the merchants' service. Those maintained by private bequests are, Hele's charity, Lanyon's charity, Orphan's aid hospital and grammar-school, Charles' alms-houses, Jory's alms-houses, lady Rogers' school, Kelway's trust. The Presbyterians have a very extensive seminary for educating girls in the tenets of their sect, supported by the contributions of their members. Among the other public buildings are to be noticed the public library, a new and elegant edifice erected by the subscribers. It is capacious and convenient, and the architectural part executed with taste and judgment by Mr. Fenelon; the front in imitation of a temple at Athens. The theatre and hotel, covering with their appendages nearly an acre of ground, have just been completed by the mayor and commonalty, at an expence of nearly 40,000*l.*; the front is very noble and has a portico, the largest in this country, containing eight columns of the Ionic order forty feet in elevation. The theatre is the handsomest country theatre in England, and is constructed almost entirely of iron. The roof is sixty-four feet span, and was made at Bristol of wrought iron bars. There are three tiers of boxes formed of cast-iron, the fronts thinly cased with wood to preserve the sound. Plans for

a new public exchange have been adopted, and are about to be acted upon, as well as are those for a new parish church. Government has several military establishments here, such as barracks, hospitals, and prisons. The latter have lately been rebuilt, and are capable of containing 3000 men; they are placed under the direction of a captain of the navy, and used as a depot for prisoners of war, from whence they are sent to Dartmoor and other inland prisons.

Plymouth was constituted a borough in the eighteenth year of Henry VI., and has sent two members to parliament, without intermission, since that period. It is governed by its own magistrates; who are a mayor, justice, and the two senior members of the bench of aldermen. In addition to the mayor and justice, the corporation consists of twelve aldermen, twenty-four common-council men, a town clerk, and a coroner. A general sessions of the peace is holden here four times in the year, where all offences, which extend to transportation for seven years, are tried, and those of minor importance are determined by the mayor at his weekly sitting in guildhall. There is a considerable trade carried on at Plymouth independently of the importation of coals, culm, corn, wine, timber, and articles for town consumption, even during war, at which times a vast deal of business arises from the sale of prizes and their cargoes, which attract purchasers from all parts of the kingdom. During peace an active trade is carried on with Newfoundland. A new and convenient pier was erected in 1790, at the expence of government, which secures the vessels lying in the pool, or inner harbour, from the violence of the waves. The market days are Mondays, Thursdays, and Saturdays. The market-place has lately been erected at an expence of 10,000*l.*, and is very extensive and commodious, comprehending three acres of ground, with an open area for a cattle market. The revenues belong to the corporation, and are considerable. Here are held two annual fairs.

The borough of Plymouth and its suburbs, according to the population report of 1811, contains 5732 houses, and 56,060 inhabitants. Of these it is specified that 12,339 were resident within the parish of St. Andrew.

This town has not acquired much literary character. Joseph Glanville, a celebrated divine and philosopher, was born here in 1636. (For an account of his life and writings, see vol. xvi. art. GLANVILLE, JOSEPH.) The brave admiral sir John Hawkins, who commanded the rear of the fleet which defeated the Spanish armada, was a native of this town (see vol. xvii.); and it was long the residence of the celebrated sir Francis Drake, who was a member of the corporation, representative to parliament, and the author of many valuable improvements in Plymouth, and its vicinity. (See vol. xii.) In the east parts of the town are the remains of the priory of White friars, granted in the 38th year of Henry VIII. to Giles Iffham. The principal gateway or entrance is in a very dilapidated state, but the ruins of the priory itself are almost extinct, and their site occupied by a smith's shop. The hospital of the Grey friars is still remaining, and is now a private house. An abbey of Cistercian friars is still standing south of St. Andrew's church, and is denominated the abbey wine vaults, the vaults being occupied for that purpose.

PLYMOUTH *Port and Harbour* is conveniently adapted for the purposes of trade, and affords an excellent road for ships of war, their prizes, and merchant vessels. The harbour is divided into several ramifications, which are distinguished by different appellations. Sutton-pool immediately adjoins the town, the buildings of which nearly encircle it. The entrance to the pool is between two large piers, erected by

PLYMOUTH.

parliamentary grants in 1791—1799. It is furrounded with public and private quays, and all ships entering it are obliged to pay certain dues on landing their cargoes. The pool is under the superintendance of a company, by whose management it has been benefited with important improvements.

Catwater harbour is formed by the estuary of the river Plym, and is capable of protecting from the south-west gales, which are prevalent, upwards of 500 ships. Part of this harbour is under the jurisdiction of the mayor and commonalty of Plymouth, the other part is subject to the controul of the present lord Boringdon, who has been at much expence in laying down moorings, buoys, &c. On the banks of the Catwater are several small villages. Cat-down, on the northern side, is famous for its lime-stone quarries: it has a shipwright's yard, various store-houses, wharfs, &c. for commercial transactions. Turnchapel, on the opposite bank, is the property of the Boringdon family, and is principally inhabited by shipwrights employed at the dock-yard here, where large ships of war are frequently repaired, and merchant and armed vessels constructed. Oreston is a populous village on the eastern banks, principally inhabited by sea-faring men. In this neighbourhood are also the beautiful villages of Upper and Lower Hooe.

Proceeding from Catwater we enter into that part of the harbour denominated the *Sound*, which is a large and capacious bay peculiarly adapted for a naval rendezvous. One disadvantage, however, attends it, of no inconsiderable kind, which is its exposure to southerly and south-westerly winds, that occasion a tremendous swell. To obviate this objection, and render it safe as well as commodious, the lords of the admiralty determined to erect a pier or breakwater, and applied to Mr. Rennie, a gentleman well fitted, from his extensive architectural knowledge, to propose an efficient and practicable remedy, and render them a plan for the purpose. The report of this gentleman has been put in execution, and the work is in a state of great forwardness. The plan of its construction is this: it is a mass of sunken stone, in length 850 fathoms, extending from about 60 fathoms east of St. Carlo's rocks, on the east, to about 300 fathoms west of the Shovel, on the west. Another pier is made from Andurn Point towards the before-mentioned breakwater, about 400 fathoms in length, having an inclined kant, forming an angle of about 120°. Of the first, about 500 fathoms in the middle are straight, and 170 fathoms at each end inclined to the straight parts in an angle of 120°. These inclined ends prevent the inrun of the sea from agitating the water, and shelter a greater extent of the sound. The two kants of the eastern end of the breakwater, and western end of the pier, repel the waves in such a manner as to prevent them from passing in any material degree through the opening between. The improvements are constructed of large blocks of stone, thrown promiscuously into the sound in the line of the breakwater, leaving them to find their own base, which is about seventy yards broad, and the top is intended to be about ten yards in width, at the level of ten feet above the low water of an ordinary spring tide. The principal part of the stone used for the works is brought from quarries at the head of Catwater, in small vessels, of from 50 to 100 tons, with a crane fixed in their decks to take out the stones, and throw them into the water. The expences necessary to complete the undertaking were estimated at 1,150,000*l.*: the quantity of stone required 2,360,000 tons. The cost of the first year was calculated at 60,000*l.*: 170,000 tons of stone have been deposited, and 500 yards in length of the mole are already apparent above low water, and the expence so far has been

considerably within the estimate presented by Mr. Rennie to the lords of the admiralty. At a more advanced state of the business, it is contemplated to erect a cut-stone pier on the top of the great breakwater, and build two light-houses on each extremity, to assist ships entering the sound.

The *Eddystone light-house*, at the mouth of the sound, five leagues south of Plymouth, is necessarily an appendage of the most important kind to the harbour, without which the entrance to it would be extremely dangerous. There is a duty payable by ships passing the light-house, which is collected at all the neighbouring ports. Merchant ships only are subject to this tax, those belonging to the king are free. For an account and history of the Eddystone light-house, see vol. xii.

Stonehouse is a populous town, containing about 5000 inhabitants, situated on the road leading from Plymouth to Plymouth-dock, and almost connecting the latter with the former by the continuation of buildings. The streets are generally irregular, but most of them paved, and the houses handsome and convenient. Stonehouse bridge, erected over a small creek of the same name, is a neat stone fabric of one arch. The revenue arising from its toll is considerable, and passes to the lords of the manor. Stonehouse has ever been the property of individuals; as early as the 27th of Henry III. it belonged to Joel de Stonehouse, and has since, by various marriages, passed into the family of Mount Edgcombe. By the last census the number of houses was found to be 566, and the population 5174. There are a chapel, work-house, and market-place; but the most important public buildings are the Royal Marine barracks, a handsome range of uniform granite edifices, in the form of a quadrangle, and capable of containing upwards of 1000 men, with their officers. At Stonehouse, and connecting it with the borough and town of Plymouth, is the Royal Naval hospital, which is an immense establishment, under the superintendance of a governor, lieutenants, and medical officers. Besides the chapel, dispensary, and officers' residences, there are seven large, commodious buildings surrounding the lawn, each containing six wards, and capable of accommodating 959 persons, officers and sailors. The sick and wounded are brought in boats from their ships, and landed at a quay immediately adjacent to the hospital. The Royal Military hospital, of a more recent erection than the former, is situated on the opposite bank of the stream, and consists of only four distinct buildings. Its government is similar to the other. Adjacent to Plymouth are several inland towns and villages of minor consequence. St. Budeaux, about five miles north of Plymouth, is a pleasant village, formerly the property of sir William Gorges, the only descendant of whom is said to be the celebrated Gorges, who commanded the Chouans in Brittany during the latter part of the French revolution. The church is a plain simple edifice, erected in the 14th century, with the materials of an older structure. Buckland-Monachorum is entitled to notice for its handsome church, consisting of a nave, side aisles, transepts, a tower, with turrets and pinnacles. The remains of the Drake family are deposited here, with several handsome monuments to their memory, as well as to that of lord Heathfield, the brave commander at the famous siege of Gibraltar. There are also the villages of Lipson, Widey, Tamerton, Crabtree, and Compton. Polwhele's History of Devonshire, folio. Beauties of England, vol. iv. Picture of Plymouth.

PLYMOUTH-Dock, sometimes denominated *Dock*, in the hundred of Roborough, and parish of Stoke-Damerell, Devonshire, is situated west of Plymouth, with the town

PLYMOUTH.

of Stonehouse only intervening. It is placed on the eastern bank of Hamoaze. The manor, excepting a part of the dock-yard, is the property of the St. Aubyn family, who inherit it from sir William Morice, secretary of state to Charles II., and mentioned by Clarendon as instrumental to the restoration. In this family rest the presentation to the living of Stoke-Damerell. The streets are regular, intersecting each other at right angles, and generally well built. The pavement is of the marble with which the neighbourhood abounds, and after a shower its veins have a beautiful appearance. Though of such considerable magnitude, it is wholly of modern date, and owes its origin and rapid increase to the establishment of the dock-yard and naval arsenals. It was made a king's yard in the latter part of the reign of William III., before which it was a mere hamlet of a few houses. The greater part of the town has been erected since 1760. The number of inhabitants in Dock is about 25,000, and the houses 2400. They are erected by the inhabitants on leases for ninety-nine years, subject to a small annual quit rent. The town and the dock-yard are defended by lines. They were commenced in the reign of George II., but the works have been much improved under an act made in the 21st of his present majesty, George III. On the north-east and south sides the town is bounded by a sod wall, about twelve feet high, which was built in 1787. The western side is skirted by the walls of the dock-yard and gun-wharf. Without the lines is a ditch from twelve to eighteen and twenty feet deep, excavated from the solid slate and limestone rock. In this line of fortification are three barrier gates; the North barrier, the Stoke barrier, and the Stonehouse barrier. Round the whole extent are planted pieces of ordnance, at regular distances. The other fortifications are a battery on mount Wise; another at the Obelisk hill; and a redoubt or block-house on mount Pleasant, without the lines, which command the whole. It is in contemplation to fortify the town regularly, and the business is actually begun; but the dock-yard may be commanded from many of the adjacent eminences, all of which must be fortified also, at an expence that would erect several distinct yards! The town, being circumscribed by this boundary of defence, does not admit of any increase of building within it. A new town without the lines, named Morice-town, is also the property of the St. Aubyn's family. Dock has two chapels, and several meeting-houses for sects of different denominations, which are very numerous. The parish church is situated about a mile from the town. There are few charitable institutions, perhaps in consequence of the recent growth of the town. The poor-house is extensive, and will contain nearly 300 persons: picking oakum for the dock-yard affords constant employment to its inmates. The town, not being incorporated, is under the jurisdiction of the county magistrates, who hold their sessions quarterly here. The inhabitants are supplied with water from the springs on Dartmoor, by an aqueduct similar to that of Plymouth. Markets are held three days in the week in the new market place, lately erected by sir John St. Aubyn. The government house is a handsome building, erected when lord Lennox commanded here; it is appropriated solely to the dispatch of military business, court-martials, &c. and has in front a grand parade. Here are eight different barrack establishments, which afford conveniences for 3000 men. The naval department consists of an admiral and rear admiral, deputy judge advocate, and commissioner for the payment of seamen's wages. Near the grand parade stands the telegraph, by which a communication is kept up with the Admiralty in London,

through thirty-six different stations. Instances have occurred of a short message being transmitted to London, and an answer returned, in fifteen minutes. (See *POST* and *TELEGRAPH*.) The dock-yard, even in its present unfinished state, is acknowledged to be one of the finest in the world. When it was first used as a naval arsenal is uncertain; but as the basin and its dock are the most ancient, and were not made till the reign of William III., it seems evident that this was a place of little consequence before that period. The wall, which separates the yard from the town, is of slate and limestone, and in some places thirty feet high. The area within the wall is seventy-one acres and thirty-six poles; including the projecting parts of the jetties. The entrance to the dock-yard from the land side is from Fore-street, by a large gate for carriages, &c., and a small one for foot passengers. No person is suffered to enter, unless well known, or in uniform, without an order from the commissioner. Immediately within the gates is the master porter's house; and close by is the chapel, the tower and one aisle of which are as old as 1700, the other aisle is of much more recent date. In front of the chapel is the military guard-office, and over that the navy pay-office. From the gates, a flat paved road, skirted with elms, leads to the officers' dwelling-houses, which are of brick, and thirteen in number. From hence to the lower part of the yard, which has been levelled from the solid rock, is a descent by a flight of steps, leading to two handsome buildings, the northernmost of which is the joiner's shop, the other is used as an office. Directly in front of these is the basin and dock, made in the reign of William III. The basin is a large excavation, in which all the boats belonging to the yard, as well as the launches employed in moving ships, are kept; the water flows into it through an opening about seventy feet wide. Within the basin is a dock, sufficiently capacious for a seventy-four gun ship; its length is 197 feet 3 inches; its width, 65 feet 10 inches; and its depth, 23 feet 1 inch. The basin is bounded on each side by jetty-heads, which are platforms projecting over the sea, supported by wooden pillars driven full of nails, to prevent the worms from perforating them. Ships of all sizes lie alongside these jetties without grounding, and here all vessels are brought to be fitted out. On the fourth jetty is a landing place, called the master attendant's stairs, where all stores returned from ships are landed, and those to be sent to them shipped off. Adjoining this jetty is the rigging house, a handsome building, 480 feet long, and three stories high, forming one side of a quadrangle. This fabric is of lime-stone, with the coars and cornices of Portland stone. Within it the rigging for the ships of war is kept in such a state of forwardness, as to be fit for use at a very short notice. Over the rigging is the sail loft, where all the sails are cut out and made. The remaining three sides of the quadrangle are store-houses, in which the various articles necessary to equip the fleets are kept. Advancing southward is a slip for hauling up and graving the bottoms of small vessels, such as sloops of war, cutters, &c. Beyond this is the Camber, a long canal, about seventy feet wide, terminating at the upper end in a basin, where boats lie; on the north side of which is the boat-house, where boats are built and repaired. Here, before the year 1768, were the bounds of the yard; all thence to the southward is still called the "new ground." The blacksmith's shop is situated south of the canal; it is a spacious building, about 210 feet square, and contains forty-eight forges. The largest anchors made here weigh five tons; they are made of iron bars forged together, and are moved in and out of the fire by the aid of cranes.

PLYMOUTH.

The quantity of coals burnt in 1802 was 876 chaldrons and 23 bushels. The anchor-wharf fronts the blacksmith's shop. Near this wharf are three slips, whereon large ships are built; and adjoining them is a boiling-house, in which the planks that are to receive a particular curve are boiled in water for a considerable time, and being afterwards applied hot to their places are immediately fastened. Northward of the slips are the mast-house and pond; in the former the different masts and yards are made of many pieces of balk, formed to fit into each other, then rounded and pressed together with iron hoops driven on red-hot. The pond is a large piece of water, inclosed from the sea by a very strong wall, of at least 10 feet in thickness, and about 380 feet long; the top of which is laid flat with large flags of coarse granite. The water flows in through two openings about forty feet wide, over which are light wooden bridges. An immense number of masts, yards, &c. are always kept in this pond, to prevent their cracking, from exposure to the sun. Near the south end of the mast-house is a small mount, generally called "Bunker's Hill," on the summit of which is a watch-house and a small battery. Under this hill is a small powder magazine, and near it a slip for building cutters and small vessels. Returning from the interior of the yard, the rope-houses first engage the attention. These are two buildings of limestone, two stories high, and twelve hundred feet long, running parallel to each other. In the upper stories twine is made, and yarns prepared for the cables, which are *laid* (twisted together) below. The largest cables that are made are 25 inches in circumference, and 100 fathoms long; they weigh 116 cwt. 1 qr. and 16 lb., and contain 3240 yarns. One of these buildings was partly consumed by an accidental conflagration in June 1812. The whole of the machinery was destroyed, and only 400 feet of the rope-house saved. The loss was estimated at 15,000*l.* In 1776 considerable alarm was excited from an attempt of John Aitken, commonly called "Jack the painter," to destroy the dock-yard with fire; he was afterwards detected in a similar endeavour at Portsmouth, and hanged. (See PORTSMOUTH.) The mould or model loft, where the different parts of ships to be built are laid down according to plans sent from the Navy Board, is in front of the store-house, and is the last building of importance in that part of the yard south of the basin. On the north jetty is a landing place, called the North-stairs, where officers not on duty generally land. Near it is a house, where pitch is kept continually boiling, to be applied to the bottoms and seams of ships. The double dock is the first of three, very near each other, for line of battle ships, and so denominated from its capability of containing two ships at the same time. The dock gates, by which the water is kept out of the docks, form, when closed, the segment of a circle, with its convex side toward the sea: they are made of timbers strongly put together and hung on each side of the mouth of the dock. As soon as a ship is taken into dock, which is always at high water, the gates are shut and locked; the water within the dock then runs out through sluices made for the purpose, till the ebb tide has ceased; the sluices are then shut, and the water which may still remain is thrown out by engines on the plan of pumps, worked by horses. The ship is taken out by opening the sluices, and suffering the water to attain an equal height within as without, when the gates are opened without difficulty. The second dock, called the Union, or North dock, is 239 feet 4 inches long, 86 feet 7 inches wide, and 26 feet 10 inches deep, and is faced with Portland stone. The New Union, or North New dock, 259 feet 9 inches long, 85 feet

3 inches wide, and 27 feet 8 inches deep, was made in the year 1789, and is on the same plan. Near the head of this latter dock is the burning place for old copper; and further northward, are the plumbers', braziers', and armourers' shops, and the bricklayers' and stone cutters' yards. Behind all this side of the yard, the rock, having never been levelled, rises very high and irregular: on it are a few sheds and storehouses. Every person belonging to the dock-yard is under the command of the commissioner, from whom all orders are received, and who has it in his power to discharge workmen for neglect of duty. The gun-wharf is separated from the dock-yard by North-corner street; it was begun in 1718 or 1719, and completed about 1785. The buildings are in general good, but very heavy, and in the Dutch style. They were projected by the late sir John Vanburgh, who was then attached to the ordnance department. The quantity of ground within the walls is four acres and three quarters. Here are two principal store-houses, of three stories high, for 80,000 muskets, pistols, and other small stores; a number of sheds for gun-carriages, &c.; a powder magazine, and a cooperage. The dock-yard, as well as the gun-wharf, is rated to the poor, and pays house and window-tax for the dwellings; but neither tithes, church rates, nor land-tax. The diversity of employments, ingenuity, and manual activity, exhibited in the various departments of the dock-yard, present a very interesting spectacle to those who have not been accustomed to appreciate the effects of human industry on a large scale. The bay or estuary of Hamoaze, on which the dock-yard is situated, is a commodious basin about four miles long, and half a mile wide, where in times of peace a very considerable part of the English navy is laid up in ordinary. The port admirals, hospital and prison ships, are always stationed here, and those that have undergone, or are about to receive repair in the dock. The ships are moored by large chains of iron, sixty fathoms long, consisting of 120 links, and having at the end a large anchor. On the banks of this harbour are other establishments of government: the powder magazine, higher up, consists of several detached stone buildings; the powder-kilns, erected for drying damaged powder; and on the bank of a creek of the harbour running to the S.W. is the South-down brewery, where all the beer for the fleet is brewed. In the vicinity of Dock are several small towns, of which Stoke is the most important. It is an ancient village, and has considerably enlarged itself within a few years. The church is situated at a short distance from the town, consisting of three aisles and a tower: the period of its erection is unknown. Moricetown, on the north side of Dock, near the ferry which crosses the Tamar, is increasing very fast in size and consequence. There are other villages in the neighbourhood, which will be treated of in our description of SALTASH. Immediately opposite to Dock is the delightful peninsula of Mount-Edgecumbe, the seat of the earl of Mount-Edgecumbe. The mansion was completed in the reign of queen Mary, and is antiquated in its appearance. It contains a few good paintings and portraits, and is pleasantly situated on the side of a wooded hill, from whence the prospect is variegated and comprehensive. The grounds occupy an area of about three miles in circumference, and are divided into parks, lawns, woods, terraces, kitchen and flower gardens. The estate became the property of the present family about the beginning of the 16th century from an intermarriage; by which connection they also became the proprietors of Stone-house. On the heights bordering the park of Mount-Edgecumbe stands Maker-church, the tower

tower of which is used as a medium for conveying signals from the admirals' ships in Hamoaze to ships in the Sound, and also to forward the information of any fleets or vessels of war in the offing, or passing up or down Channel. Polwhele's History of Devon, folio. Beauties of England, vol. iv. Picture of Plymouth and Dock.

PLYMOUTH, a maritime county, in the eastern part of the state of Massachusetts, containing 35,169 inhabitants, and subdivided into 18 townships, of which Plymouth is the chief. Within the counties of Plymouth and Bristol there were, in 1796, in actual work, 14 blast and six air-furnaces, 20 forges, seven slitting and rolling mills, besides a number of nail shops, and others for common smithery. These furnaces, supplied from the neighbouring mines, produce annually from 1500 to 1800 tons of iron-ware. The forges, at an average, manufacture more than 1000 tons annually, and the slitting and rolling mills at least 1500 tons. The manufactures of these mills have given rise to various others dependent upon them, such as cut and hammered nails, spades, and shovels, card teeth, saws, scythes, metal-buttons, cannon-balls, balls, fire-arms, &c. In these counties are also manufactures of hand-bellows, combs, sheet-iron for the tin-manufacture, wire, linseed oil, snuff, stone and earthen ware. The iron-works, called the Federal furnaces, are seven miles from Plymouth harbour.

PLYMOUTH, the capital of the above county, is a post-town and port of entry, 42 miles S. from Boston, to which belongs an extensive township, more than 80 square miles, is about 16 miles in length, and more than five in breadth, containing, by the census of 1791, 2495 inhabitants, and in 1810, 4228. The town, or principal settlement, containing more than two-thirds of the inhabitants, lies on the N.E. part of the township, near a stream, called the "Town-brook," which flows from a large pond, bearing the name of "Bellington sea." The principal street crosses the stream, and is intersected by three cross streets, extending to the shore; another street runs westerly on the N. side of the brook. The town is compactly built, and contains about 200 dwelling houses, a handsome meeting-house, court-house, and gaol. Here are two precincts, one including the town and the district of Hobbs-Hole and Eel river; the other at Monument Ponds, a village about seven miles E. from the town, beyond the highlands of Monument. The soil near the coast is generally good; the residue of the township is barren, and remains a forest, consisting partly of pine and partly of oak. The harbour is spacious, but shallow; formed by a long and narrow neck of land, called "Salthouse beach," extending southerly from Marshfield and terminating at the Gurnet head, and by a smaller beach within, running in an opposite direction, and connected with the main land near Eel river, about three miles from the town. On the Gurnet is a light-house, and on Salthouse-beach is placed one of the huts, erected and maintained by the Humane Society of Massachusetts, for the reception and relief of shipwrecked mariners.

The principal business of the town is the cod-fishery, employing about 2000 tons of shipping and about 300 men annually. Many of the fishing vessels make voyages to the southern states in the winter season. The exports in 1795 exceeded 70,000 dollars, and in 1796 amounted to near 130,000 dollars. The produce of the fishery was formerly sold at Boston, or Salem; but it is now almost wholly exported from the town. The proceeds of the foreign voyages are generally conveyed to Boston for a market. During the war for independence, Plymouth suffered much, and was reduced to a state of great distress; but it has

since revived, and both the town and its environs have been improved. A stage passes to Boston twice a-week, and an aqueduct is constructed for bringing fresh water to the inhabitants. The township abounds with ponds (amounting to more than 100) and streams. Bellington sea covers near 300 acres, about two miles from the town, and from it runs a stream, which supplies the aqueduct. South pond is much larger. Many of the ponds abound with white and red perch, pike, and other fresh-water fish, and in the numerous brooks which run into the sea are found excellent trout. These ponds and streams are frequently scenes of amusement for parties of both sexes, in the summer season. At the villages of Monument Ponds and Eel river, and in some other parts of the township, many of the inhabitants are farmers; and in the town the gardens are numerous and well-cultivated, and aided by the aqueduct will furnish a supply adequate to the wants of the inhabitants.

The situation of the town is pleasant and healthful, but the easterly winds of the spring are noxious. Although the market is not regularly supplied, fowl, fish, poultry, and wild fowl are plentiful, and cheaper, perhaps, than in any other sea-port of the same size. The people are sober, industrious, and friendly. Plymouth is the first settlement in New England, in 1620, but is peopled, principally, by the descendants of the ancient stock, intermixed with a few foreigners. The rock on which their forefathers first landed, was conveyed, in 1774, from the shore to a square in the centre of the town. Although fishing and foreign commerce engage at present almost the whole native capital of the town, a variety of circumstances will probably render it, at some future period, a considerable manufacturing town.

PLYMOUTH, a town in Litchfield county, Connecticut, containing 1882 inhabitants.—Also, a port and half-shire town in Grafton county, New Hampshire, on the S. side of Baker's river, at its mouth, where it falls into the river Pemigewasset; 45 miles N. of Concord; incorporated in 1763, and containing 937 inhabitants.—Also, a town of New York, in Onondago county; lying about 12 miles S.E. of Geneva, on a beautiful declivity on the E. side of Seneca lake, and commanding a view of the whole lake. The situation is healthful and pleasant, well watered by copious springs: more than twenty houses were built here in 1796. The new state road intersects this town, and here is a ferry across the lake to another thriving town on the opposite side.—Also, the name of two townships in Pennsylvania, one in Luzerne county, and the other in that of Montgomery; the former has 765, and the latter 895 inhabitants.—Also, a town of North Carolina, about 20 miles from Edenton, and a place of considerable trade; the navigation is free and open, and the two places have a constant communication across Albemarle sound.—Also, a settlement on the S. peninsula of St. Domingo, in the dependence of Jeremie.—Also, a township in Windsor county, Vermont, formerly Saltash, 12 miles W. of Windsor; containing 834 inhabitants.

PLYMOUTH Town, a town in the island of Tobago. N. lat. 10° 10'. W. long. 60° 3'.

PLYMOUTH Marble, among our Artificers, a term used for a sort of marble dug in great plenty about Plymouth, and in some parts of Devonshire, where it lies in very thick strata, and whence it is brought in large quantities to us; and when wrought looks little less beautiful than some of the Italian marble.

It is very hard and firm, and of a beautiful texture; its ground is a blueish-white, and its variegations are principally a pale red, and in smaller quantities brown and yellow: these

these lie in very orderly beds, and often there is a very agreeable glow of a faint red diffused through the whole substance. It is remarkable even in its whole structure, and is therefore capable of a more than ordinarily elegant polish.

PLYMPTON, a township in Plymouth county, Massachusetts; 45 miles S.E. of Boston, containing 900 inhabitants.

PLYMPTON-MAURICE, or **EARLS-PLYMPTON**, a borough and market town in the hundred of Plympton, and county of Devon, England, is 216 miles W.S.W. from the metropolis, and 39 miles S.W. from Exeter. According to the population returns of 1811, it contains 92 houses, and 715 inhabitants. It is one of the stannary towns, and formerly constituted part of the honour of Plympton, to which no fewer than eighty-nine knight's fees were appendant, when it was granted by Henry I. to Richard de Rivers, or Redvers, earl of Devonshire. That nobleman built here a magnificent castle, and made it the capital seat of his barony. He and his successors likewise conferred upon the town considerable privileges. Baldwin de Rivers granted it a charter of incorporation, which was successively confirmed and extended by Edward III., Richard II., and Henry V. and VI. Queen Elizabeth granted a new charter, under which the town is now governed by a mayor, a recorder, eight aldermen, a bailiff, and a town clerk. The mayor is invested with the powers of a justice of the peace, and holds a court of record at stated intervals.

Plympton sends two members to parliament, and has done so, though irregularly, since the reign of Edward I. These are elected by the mayor and free burgesses, who are estimated at one hundred in number. The mayor is the returning officer. The market day here is Saturday every week; besides which there are four annual fairs. The houses are chiefly disposed in two streets, extending at right angles with each other in the form of the Roman letter T. The church is only a chapel annexed to the church of Plympton St. Mary, an adjoining parish and village. The living is a curacy, in the patronage of the dean and canons of Windsor. The other public buildings are a guildhall and a free-school. The guildhall is an ancient structure supported on stone pillars, and contains, among other portraits, one of sir Joshua Reynolds, painted by himself. The free-school was erected in 1664, by one of the trustees of Elizeus Hele, esq. of Fardel, who bequeathed 1500*l.* per annum, to be expended in charitable purposes. Of this school, the father of sir Joshua Reynolds was master for many years, and in the master's house belonging to it the celebrated artist himself was born on the 16th July 1723. See **REYNOLDS**.

PLYMPTON St. Mary, above-mentioned as adjoining to Plympton-Earls, is a village and parish of very considerable antiquity. The church was formerly collegiate for a dean or provost, and four prebendaries with other ministers. This college is said to have been of the foundation of one of the Saxon kings. It was dissolved by William Warlewast, bishop of Exeter, on the refusal of its religious to discard their wives in obedience to the decrees of the synod, held in London A.D. 1102, by which celibacy was enjoined to the clergy. That prelate afterwards settled here a prior and canon regular of the order of St. Augustin. The benefactions conferred on this priory by earl Baldwin and others were immense, and rendered it the richest monastic institution in the diocese of Exeter. Its revenues at the time of the dissolution were valued at 912*l.* 12*s.* 1*d.* per annum. The site was granted by queen Elizabeth to Arthur Champenon, esq. Here was also an hospital for lepers. The parish of Plympton St. Mary, exclusive of

Plympton-Earls, contains, according to the parliamentary returns of 1811, 272 houses, 1727 inhabitants.

Near Plympton is Boringdon, the ancient seat of the Parkers, and now the property of their representative John Parker, earl of Boringdon. The mansion which was built in the fourteenth century has been converted into a farmhouse, and has consequently undergone great alteration and diminution since the removal of the family seat to Saltram, in the neighbourhood, by lady Catharine Parker. Saltram is remarkable for the beauty of its situation; for exclusive of the diversity of landscape displayed by the surrounding pleasure grounds, the prospects which it commands "of Plymouth sound, the town, citadel, Mount Edgcombe, and the endless variety of effects peculiar to the sea and harbour, are extremely interesting and amusing." The house is the largest in the county, and contains a valuable collection of paintings by ancient and modern masters. Beauties of England and Wales, vol. iv. by John Britton, F.S.A. and E.W. Brayley.

PLYNTERIA, Πλυντήρια, in *Antiquity*, a festival in honour of Aglaurus, the daughter of king Cecrops, or rather of Minerva, who had from that lady the name of Aglaurus. These were the holidays of Minerva, which was reckoned unlucky, at which time, according to Xenophon, they shut up the temples of that goddess. It was expressly forbidden to pursue any work whatever on the day of this festival, even in cases of necessity. It was then allowable by the law of Solon to swear by the three names of Jupiter Propitious, Expiator, and Defender. For the ceremonies observed at this solemnity, see Potter, *Archæol. Græc. lib. ii. cap. 20. tom. i. p. 425.*

PNEUMA, Πνευμα, in Hippocrates, sometimes imports spirit, air, or vapour, and frequently it signifies the breath, that is, the air drawn in by inspiration, and expelled during expiration. But pneuma, by the above quoted author, is often used to express a difficult, short, and laborious respiration.

PNEUMATICS, **PNEUMATICE**, called also *Pneumatology* and *Pneumatosophy*, the doctrine and contemplation of spirits, and spiritual substances.

The word is formed of the Greek πνευμα, *spiritus, breath*; whence, from the different acceptations of that word either as an incorporeal substance, or as air, there arise two sorts of pneumatics.

PNEUMATICS, in the *Schools*, is frequently used for the doctrine of spirits; as God, angels, and the human soul. See **SPIRIT**.

In this sense pneumatics coincide with what we otherwise call metaphysics.

PNEUMATICS is more commonly used among us for the doctrine of the air; or that part of natural philosophy which treats of the nature, properties, and effects of the air.

Some make pneumatics a branch of mechanics; because it considers the air in motion, with the effects of it. It is certainly a sister of hydrostatics; the one considering air in the same manner that the other does water.

Wolffius, in lieu of pneumatics, uses the word *aerometry*, *q. d.* the art of measuring the air.

The doctrine and laws of pneumatics will be found under **AIR**, **ATMOSPHERE**, **ELASTICITY**, **GRAVITY**, **COMPRESSION**, **CONDENSATION**, **RAREFACTION**, **EXPANSION**, &c.

PNEUMATIC Engine, *Machina* or *antlia pneumatica*, denotes the air-pump.

PNEUMATIC Sect of physicians, a subdivision of the methodic sect, which took place at Rome, and is ascribed to two or three different persons, who are severally esteemed its founders.

founders. The chief distinction of the pneumatic sect, consisted in referring to a particular spirit, or *pneuma*, which they considered to arise from the heart and arteries. See *MEDICINE, History of*.

PNEUMATOCELE, from *πνευμα*, *wind*, and *κελρα*, *a tumour*, in *Surgery*, a swelling containing air: also a wind rupture; a complaint which is spoken of by many surgical writers; but has no real existence. Hernial tumours do, indeed, sometimes include air, which is combined within the protruded bowel, or else produced in the cellular membrane from putrefaction in the sloughing state of the disease. Yet it is not the accidental presence of such air that constitutes the rupture or hernia; but the protrusion of some of the viscera from the cavity of the abdomen.

PNEUMATODES, a word used by Hippocrates to express a person who fetches his breath short and quick: and sometimes for one who has his belly or ilia much distended by flatulencies. *Pneumatias* is also used in the same double sense.

PNEUMATOMACHI, *Πνευματομαχοι*, in *Ecclesiastical History*, ancient heretics, so called, because they opposed the divinity of the Holy Spirit, placing him in the number of creatures.

PNEUMATOMPHALOS, from *πνευμα*, *wind*, and *ομφαλος*, *the navel*, in *Surgery*, a rupture of the navel, containing air, or supposed to be produced by wind.

PNEUMATOSIS, in *Medicine*, from *πνευμα*, *air*, a term denoting large accumulations of air in any cavity of the body. It may include, therefore, not only *tympanites*, but *emphysema*. In this sense Sauvages employs the term, and describes four species of pneumatosis; the first he calls *spontanea*, as it arises without any evident cause; the second, *traumatica*, which originates from wounds of the lungs, whence the air is permitted to escape into the cellular membrane of the whole body; the third, *venenata*, arising from poisons; and the fourth, *hysterica*, when the air is confined to the stomach and intestines. (See his *Nofol. Method. clafs x. gen. 5.*) See also *EMPHYSEMA*.

PNEUMONANTHE, in *Botany*, a name given by many botanical writers to a species of gentiana, called also by some the *calathian* violet.

PNEUMONIA, in *Medicine*, from *πνευμων*, *the lungs*, signifies an inflammation of the lungs and its investing membrane. It includes, therefore, both the forms of the disease, peripneumony and pleurisy. See *PERIPNEUMONY*.

PNEUMONICS, *Πνευμονικα*, medicines proper in diseases of the lungs, in which respiration is affected.

The word is formed from the Greek *πνευμων*, *lungs*, or *πνευμα*, *spiritus, breath*.

Of this number are fulphur, lung-wort, hyffop, ground-ivy, and colt's-foot; they are used in phthises, asthmas, peripneumonies, pleurifies, &c.

PNEUMORA, in *Entomology*, a genus of insects of the order Hemiptera. The generic character is; body ovate, inflated, diaphanous; head inflected, armed with jaws; thorax convex, carinate beneath; wing-cafes deflected, membranaceous; legs formed for running. There are three species of this genus, and they all appear to consist of a mere hollow inflated membrane; by rubbing together their ferrate or toothed legs, they make a shrill kind of noise morning and evening; and they follow a light; they are so nearly allied to the cricket tribe, that they have been ranked by Fabricius with the *Gryllus* genus.

Species.

IMMACULATA. Green spotted with white; wing-cafes
VOL. XXVII.

immaculate. It inhabits the Cape of Good Hope. In Fabricius it is the *Gryllus papillofus*.

MACULATA. Wing-cafes green, with square white spots.

6-GUTTATA. Wing-cafes green, with two white spots; abdomen with three white spots on each side. This is found at the Cape of Good Hope.

PNIGITIS TERRA, in the *Materia Medica of the Ancients*, a name given at different periods of time to two different species of earth: the terra pnigitis of Dioscorides and Pliny being a grey marle, and the pnigitis of Galen a black clay.

The last of these is said to be a very valuable astringent, and is found in many parts of this kingdom, particularly in the neighbourhood of London, and well deserving to be introduced in the practice of physic.

PNIGMOS, from *πνιγε*, *I suffocate*, in *Medicine*, a kind of suffocation, from whatever cause: it is very often used to express that of hysterical fits in women.

PNIX, a word used by physicians to express the suffocation from hysterical fits, or any other cause.

PO, in *Geography*, *Padus*, (which see,) a river of Italy, which rises in mount Viso, at the N.W. part of the marquisate of Saluzzo, seven miles N. of Chateau Dauphin, traverses a part of the marquisate of Saluzzo, the province of Chieri, the duchy of Montferrat, the Milanese, Mantuan, and Ferrarese, and runs into the gulf of Venice, by a great number of mouths.

Po, *Department of*, one of the six departments into which Piedmont was divided, after having been united to the French republic, August 26, 1802, the other five being Doire, Sesia, Marengo, Tanara, and Stura. This department is formed of the district of Turin, quatre-vallois, and the marquisate of Susa, in N. lat. 45°, lying between Doire and Stura, and on the W. and N.W. bounded by the Alps, containing 264 square leagues, and 395,193 inhabitants. It is divided into three circles, *viz.* Susa, including 61,236 inhabitants; Turin, 232,313; Pignerol, 101,634. Situated at the foot of the Alps, and broken into vallies, hills, and plains, the soil of this department is of various qualities. The plains and vallies, in general, are fertile. In the mountains are mines of copper, lead, iron, quarries of marble, stone, slate, &c.

Po, *Lower*, a department of the new kingdom of Italy, composed of the duchy of Ferrara, and the valley of Comacchio.

Po, *Upper*, a department of Italy, formed of the Cremonese, the Cremasco, and the Lodofan.

Po, *the Vale of the*, one of the four regions into which Italy may be divided; it extends about 260 miles in length, and in breadth, where widest, 150. It is bounded by the Alps and Apennines on the N., W., and S., and on the E. lies open to the Adriatic. The second region is the tract inclosed by the Apennines, forming the Roman and Tuscan territories. The third is confined to the Campania Felix, and its immediate dependencies, such as the borders and the islands of the bay of Naples, and of the plains of Pœstum. The last consists of Abruzzo, Apulia, Calabria, and the southern extremities of Italy.

The first of these regions has been represented by many, as perhaps the most fertile and the most delicious territory in the universe. It owes this fertility to the many streams that descend from the bordering mountains, and furnish a constant supply to the majestic river that intersects it. Mr. Eustace, in the second volume of his "Classical Tour," avoids the name frequently given to the plains of the Po or of Milan. *Lombardy* (which see) is, he says, a barbarous
5 D appellation,

appellation, derived from one of the fiercest tribes that invaded and wasted this delicious region. After more than two centuries of devastation and restless warfare, they were exterminated by Charlemagne; and our author does not see why their name should survive their existence, or why a barbarous term should displace a Latin appellation.

Po, a city of China, of the second rank, in Kiang-nan; 260 miles S.S.W. of Peking. N. lat. $33^{\circ} 45'$. E. long. $115^{\circ} 14'$.—Alfo, a town of China, of the third rank, in Chan-tong; 262 miles S. of Peking. N. lat. $35^{\circ} 48'$. E. long. $115^{\circ} 14'$.

POA, in *Botany*; $\rho\alpha\alpha$, a general name for *grafs*, or *herbage*, is appropriated by Linnæus to this, one of the most common and copious genera of the *grafs* family.—Linn. Gen. 34. Schreb. 49. Willd. Sp. Pl. v. 1. 385. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 95. Prodr. Fl. Græc. Sibth. v. 1. 53. Schrad. Germ. v. 1. 278. Ait. Hort. Kew. v. 1. 153. Brown Prodr. Nov. Holl. v. 1. 179. Pursh North-Amer. v. 1. 78. Juss. 32. Lamarck Illustr. t. 45. Michaux Boreal-Amer. v. 1. 67.—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two ovate, pointed, awnless valves, collecting the numerous florets into a two-ranked ovate-oblong spikelet. *Cor.* of two ovate, sharpish, concave, compressed valves, rather longer than the calyx, membranous at the edges. Nectary of two acute or torn leaflets, gibbous at the base. *Stam.* Filaments three, capillary; anthers forked at each end. *Pist.* Germen superior, roundish; styles two, reflexed, villous; stigmas feathery. *Peric.* none, the corolla unites itself to the seed, and does not separate. *Seed* one, oblong, pointed, compressed at each side, covered by the corolla.

Obs. In some species the florets are connected at the base by a fine web of folded silky threads.

Ess. Ch. Calyx of two valves, many-flowered. Spikelet rounded at the base. Corolla of two ovate, rather acute, awnless valves, membranous at the edge.

Of this large and valuable genus the 14th edition of Syst. Veg. contains 33 species; Willdenow reckons up 61; but we suspect the last of these, *P. plumosa*, not to be different from his n. 38, the Linnæan *tenella*. The British species are 18, which we shall particularize, along with a few of the most remarkable exotic ones. Mr. Brown describes 21 *Poæ*, mostly new, in his New Holland Prodromus.

P. aquatica. Reed Meadow-grafs. Linn. Sp. Pl. 98. Willd. n. 1. Engl. Bot. t. 1315. Curt. Lond. fasc. 5. t. 12. Knapp. t. 44. (Gramen aquaticum majus; Ger. Em. 6.)—Panicle erect, branched, lax. Spikelets six-flowered, linear. Florets obtuse, with seven ribs.—In ditches and about the banks of rivers, perennial, flowering in July, conspicuous for its large size and reedy aspect. Its colour is a light, not at all glaucous, green. *Stem* five or six feet high. *Leaves* flat, acute, broad, straight, rough at the edges and keel, with a nearly smooth sheath, and a short, entire, very blunt *stipula*. *Panicle* very large and numerously branched, the subdivisions rather zigzag, rough. *Calyx* almost equal, whitish, polished. *Florets* from five to eight, scarcely more, nearly cylindrical, somewhat distant, obtuse, rough, purplish at the outer part.

Cattle are said to be fond of this *grafs*, though coarse. It usually makes a principal part of marsh-land hay.

P. fluitans. Floating Meadow-grafs. Scop. Carn. ed. 2. v. 1. 73. Fl. Brit. n. 2. Ait. n. 2. Engl. Bot. t. 1520. Knapp. t. 45. (*Festuca fluitans*; Linn. Sp. Pl. 111. Curt. Lond. fasc. 1. t. 7. Mart. Rust. t. 113. Willd. Sp. Pl. v. 1. 426. *Glyceria fluitans*; Brown Prodr. N. Holl. v. 1. 179.)—Panicle branched, divaricated. Spike-

lets close-pressed, cylindrical, many-flowered. Florets obtuse, with seven ribs, and intermediate ones at the base.—In ditches and flow rivulets, perennial, flowering throughout the summer, in most parts of Europe. Mr. Brown found it at Port Jackson, New South Wales, the seeds probably having been carried from England by accident. This writer has separated it as a genus from *Poa*, chiefly because of the *stigmas* being repeatedly branched, and the *nectary* a solitary fleshy scale. But the neighbouring species of *Poa*, wanting these characters, seem too strictly akin to this to allow of such a separation. The *root* creeps extensively. *Stems* spreading widely, floating for the most part, with their lower *leaves*, on the still surface of the water. *Sheaths* long, compressed, striated, smooth. *Stipulas* short, triangular, jagged. The larger branches of the *panicle* spread widely, and are accompanied by short more erect ones. The short intermediate ribs, at the bottom part of each *floret*, afford a peculiar character.

P. difflans. Reflexed Meadow-grafs. Linn. Mant. 32. Willd. n. 55. Ait. n. 22. Engl. Bot. t. 986. Knapp. t. 47. (*P. retroflexa*; Curt. Lond. fasc. 6. t. 10. *P. fallina*; Pollich. Palat. v. 1. 89.)—Panicle branched, spreading; the branches at length reflexed. Spikelets of five, very obtuse, slightly five-ribbed, shining florets.—In meadows, and amongst rubbish, chiefly near the sea, in various parts of England. Jacquin found it in Austria. The *root* is fibrous, perennial. *Stems* several, about a foot high, decumbent at the lower part, striated, smooth to the touch. *Leaves* glaucous, flat, with long *sheaths*, and a blunt emarginate *stipula*. *Panicle* erect, with branches of various lengths, several together, remarkable for being strongly bent downwards as they advance in age. *Florets* much like the *aquatica* in their form and arrangement, but with only five ribs. Vahl in his Symbolæ, v. 2. 19, most unaccountably confounds this *grafs* with Gouan's *P. divaricata*, Willd. n. 56.

P. maritima. Creeping Sea Meadow-grafs. Hudf. 42. Willd. n. 39. Ait. n. 16. Engl. Bot. t. 1140. Knapp. t. 46. Fl. Dan. t. 251.—Panicle branched, rather close. Spikelets of five bluntish, nearly cylindrical, slightly five-ribbed florets. *Root* creeping.—Native of sandy salt-marshes, in various parts of Europe, flowering in July. Akin to the last, but the creeping *root*, branches of the *panicle* erect after flowering, rarely divaricated, and longer, more acute *florets*, distinguish the present species.

P. dura. Hard Meadow-grafs. Scop. Carn. ed. 2. v. 1. 70. Sm. Prodr. Fl. Græc. Sibth. n. 181. Schrad. Germ. v. 1. 284. Hoff. Gram. Austr. v. 2. 53. t. 73. (*Cynofurus durus*; Linn. Sp. Pl. 105. Willd. Sp. Pl. v. 1. 413. Pollich. Palat. t. 1. f. 1.)—Spike nearly simple. Spikelets sessile, alternate, crowded, rigid, obtuse, compressed, all turned one way, of about five elongated ribbed florets.—Native of sandy waste ground in the south of Europe, flowering in May and June. *Root* annual, of many long simple fibres. *Stems* numerous, two to four inches high, spreading in every direction, leafy, rigid, sometimes branched at the base. *Leaves* glaucous. *Spike* ovate, an inch long, rigid, its zigzag smooth stalk visible at the back only. *Spikelets* about a dozen, linear-oblong, glaucous, all their glumes strongly ribbed, and each bordered with a broad white membrane. This species is closely allied to the preceding and the following ones, nor has it any character of *Cynofurus*. It has not been found in Britain.

P. procumbens. Procumbent Sea Meadow-grafs. Curt. Lond. fasc. 6. t. 11. Engl. Bot. t. 532. Knapp. t. 49. Fl. Brit. n. 5. Ait. n. 3. (*P. rupestris*; With. 146. t. 26. *Gramen maritimum*, *paniculis asperis loliaceis*;

Bocc. Mus. 135. t. 95.)—Panicle lanceolate, dense, rough, turned one way; common stalk round. Spikelets cylindrical, of about five bluntish, ribbed florets.—Native of sandy inundated waste ground, near the sea, in England, Holland, and Sicily, flowering in summer. The root is annual. Whole plant much like *P. dura*, but more slender, taller, and less rigid, with a doubly compound panicle, not a spike, and far more numerous, smaller, cylindrical spikelets.

P. rigida. Rigid Meadow-grafs. Linn. Sp. Pl. 101. Willd. n. 40. Curt. Lond. fasc. 2. t. 4. Knapp. t. 48. Engl. Bot. t. 1371.—Panicle lanceolate, dense, smooth, two-ranked, turned one way; common stalk bordered. Spikelets of seven cylindrical, ribbed florets.—Common on the tops of dry walls, and in barren sandy ground, annual, flowering in June. The whole plant is four or five inches high, of a peculiarly rigid, elastic, wiry habit, and purplish-brown hue. Every part is smaller than in the last.

P. divaricata. Straggling Meadow-grafs. Gouan Illustr. 4. t. 2. f. 1. Willd. n. 56. Desfont. Atlant. v. 1. 75. (Gramen phalaroides, sparsa paniculâ, minimum angustifolium; Barrel. Ic. t. 44. f. 1.)—Panicle capillary, divaricated, with corymbose branches. Flower-stalks club-shaped. Florets four. Leaves brittle-shaped.—Native of the south of France and of Barbary. A small, delicate, slender, annual grass, with the habit of *Aira caryophyllea*, for which the plate of Barrelier has been quoted, a circumstance that has caused some confusion. It flowers in the spring, and has a very elegant aspect. The thickened flower-stalks, and the crowded little shining spikelets, are characteristic of this species.

P. Eragrostis. Spreading Meadow-grafs. Love-grafs. Linn. Sp. Pl. 100. Willd. n. 24. Ait. n. 12. Sm. Fl. Græc. Sibth. v. 1. 57. t. 73. Cavan. Ic. t. 92. (*P. megastachya*; Schrad. Germ. v. 1. 288. *Briza Eragrostis*; Linn. Sp. Pl. 103. Willd. Sp. Pl. v. 1. 405. Schreb. Gram. t. 39. *G. eranthemum*, seu *eragrostis*; Barrel. Ic. t. 43.)—Panicle erect, branched, spreading. Spikelets linear, many-flowered. Florets tumid, with three keels. Stipula brittle.—Native of Greece, Barbary, Italy and Switzerland, though not known to Haller as a Swiss plant; see the following species. A very elegant annual grass, with numerous stems, from one to two feet high, quite smooth. Leaves spreading, grass-green; their stipula of many fine hairs. Panicle ample, loose, much branched. Spikelets linear, alternate, stalked, green or purplish, shining. Florets from ten to thirty-six, imbricated, ovate, tumid, roughish, with three distant ribs or keels. The above two plants of Linnæus are certainly one and the same, differing merely as to number of florets. The ripe seed being unconnected with the corolla, makes the plant a *Poa*, not a *Briza*.

P. elegantissima. Elegant Meadow-grafs. (*P. Eragrostis*; Villars Dauph. v. 1. 135. Schrad. Germ. v. 1. 287. Schreb. Gram. t. 38. P. n. 1450; Hall. Hist. v. 2. 219. Gramen phalaroides, sparsa Brizæ paniculâ minus; Barrel. Ic. t. 44. f. 2. *G. paniculis elegantissimis*, minimum; Scheuchz. Agr. 192. t. 4. f. 2.)—Panicle erect, branched, capillary, spreading. Spikelets lanceolate, scarcely ten-flowered. Florets compressed, keeled, three-ribbed. Stipula brittle.—Native of Switzerland, France, and Italy. About one-third the size of the foregoing, with sharper leaves, dark purple tapering spikelets, and about a quarter of the number of florets, which are compressed and keeled, with one obsolete rib at each side, near the edge. This is commonly taken for *P. Eragrostis* of Linnæus, but erroneously, he having never been acquainted with the grass before

us, though he cites some of its synonyms for his *P. Eragrostis* above described.

P. compressa. Flat-stalked Meadow-grafs. Linn. Sp. Pl. 101. Willd. n. 42. Ait. n. 18. Knapp. t. 57. Engl. Bot. t. 365. Hofst. Gram. Austr. v. 2. 51. t. 70.—Panicle dense, turned one way. Stem ascending, compressed. Florets angular, connected at the base by a folded web.—Common in dry fields and on walls, in Europe as well as America. Mr. Pursh says it is known in the last-mentioned country by the name of Blue Grass. It flowers with us in July and August, and has a perennial creeping root. The whole plant is rather glaucous, about a foot high, readily known by its very flat stem, and dense panicle, whose branches spread but for a short period, while in full blossom. Florets from three to nine, closely imbricated, ovate, angular, three-ribbed, bluntish, purple just under the white membranous tip, connected together at the bottom by a set of fine cottony fibres, shorter than in some other species.

P. alpina. Alpine Meadow-grafs. Linn. Sp. Pl. 99. Willd. n. 2. Ait. n. 4. Engl. Bot. t. 1003. Hofst. Gram. Austr. v. 2. 49. t. 67. Knapp. t. 50 and t. 117.—Panicle loose. Spikelets heart-shaped, of about four flowers. Glumes ovate, rather falcate, not connected by a web. Lower stipulas very short.—Native of the mountains of Lapland, Germany, and Scotland, as well as of the Bithynian Olympus, flowering in summer. Root tufted, perennial, with smooth fibres. Stems from four to twelve inches high; leafy below; smooth, shining, often purplish, above. Radical leaves forming a dense tuft; those on the stem furnished with much longer sheaths as well as stipulas. Panicle spreading, short, somewhat ovate, with angular, nearly smooth, branches. Spikelets broad, shining, elegantly variegated with green, white, and a purplish brown. "Florets ovate, acute, membranous at the edge, the lower part of which is silky, and the keel still more so;" several longish hairs, but no complicated web, are found at the base. In wet seasons the flowers are changed into buds, forming young plants, as shewn in Scheuchz. Agrost. t. 4. f. 14, and in Engl. Bot.

P. flexuosa. Zigzag Meadow-grafs. Sm. Fl. Brit. 101. Engl. Bot. t. 1123. Knapp. t. 51. Ait. n. 5. (*P. laxa*; Willd. n. 3. Schrad. Germ. v. 1. 291.)—Panicle dense, somewhat drooping, zigzag. Spikelets three-flowered. Glumes ovate, connected by a web. Stipulas all lanceolate.—Discovered on the Scottish mountain of Ben Nevis, by the late Mr. J. Mackay, flowering in July. Schrader mentions it as a native of various alpine situations in Germany. The root is somewhat creeping. This species is of a more slender habit, and paler glaucous aspect, than the *alpina*, and differs essentially in the above characters. The glumes are not silky at the keel nor margin.

P. bulbosa. Bulbous Meadow-grafs. Linn. Sp. Pl. 102. α and γ , not β . Willd. n. 50. Ait. n. 21. Engl. Bot. t. 1071. Knapp. t. 53, with the root of another species. (*G. vernum*, radice alcalonitidis; Vaill. Paris. t. 17. f. 8.)—Panicle slightly zigzag. Spikelets four-flowered. Glumes veinless, connected by a web. Leaves finely serrated. Stem bulbous at the base.—Native of France, Italy, Germany, Switzerland, and England, in dry sandy places. With us it is found only on the sandy sea-coast, over which its little dry bulbs are blown in various directions, during summer, till the first rains of autumn make them vegetate, and take deep root. The plants then yield abundance of short dense herbage, a welcome spring food for cattle, and flower in April or May; having, meanwhile, formed young bulbs, like a minute kind of garlick, which are dispersed, like their predecessors, after the leaves wither. The stems are

naturally three or four inches high; in a garden they rise to above a foot, and the *leaves* are long in proportion. The *ferrated foliage*, the *bulbs*, the woolly web connecting the *florets*, and their broad veinless *glumes*, clearly ascertain this species. The *panicle* is small, hoary or silvery, and purplish.—We have gathered this grass for the most part in a viviparous state, on the open ground near St. John Lateran, at Rome, in the early spring. This is probably the variety β of Schrader and other German authors; but the β of Linnæus is a very different, much taller, and greener grass, with long and extremely narrow *leaves*, an elongated *panicle*, of numerous viviparous *flowers*, and peculiarly rough *flower-stalks*. Oriental specimens are in the Linnæan collection, apparently sent by Hasselquist. This is what Scheuchzer has described in his *Agrostographia* 211, and what Morison has figured, sect. 8. t. 5. f. 14, after Bauhin's *Theatrum* 32. But the best representation is in Barrelier, t. 703. f. 2. We are afraid to describe this as a species, without seeing some spikelets in a natural state; but we are persuaded it is perfectly distinct, and that there are, besides, other bulbous *Poa*, hitherto confounded with the true *bulbosa*.

P. casia. Sea-green Meadow-grass. Fl. Brit. 103. Engl. Bot. t. 1719. Ait. n. 7.—Panicle spreading. Spikelets ovate, five-flowered. Glumes lanceolate, silky-edged, unconnected by any web. Stipula very short and blunt.—Native of the Highlands of Scotland, flowering in June and July. It seems unknown in every other country. The *root* is perennial, fibrous, tufted. Whole plant very glaucous. *Stems* erect, about a foot high, round, smoothish, with two joints near the bottom. *Leaves* bluntnish, flat, rough to the touch, except on the back near the base. *Sheaths* roughish, about as long as the leaves. *Stipula* sometimes variable in size and shape. *Panicle* much branched, rough. *Flowers* variegated with purple, white, and green, each outer valve marked with a silky line of hairs, near the edges, and on the keel; but there is no complicated web connecting the florets. The doubtful reference to Withering is to be struck out of Fl. Brit., as belonging to our *glauca*, hereafter mentioned, which Mr. Knapp has by mistake figured for *casia*.

P. trivialis. Roughish Meadow-grass. Linn. Sp. Pl. 99. Willd. n. 6. Ait. n. 8. Curt. Lond. fasc. 2. t. 6. Knapp. t. 54. Engl. Bot. t. 1072. (*P. dubia*; Leers Herborn. 28. t. 6. f. 5.)—Panicle spreading. Spikelets three-flowered. Glumes lanceolate, five-ribbed, connected by a web. Stem roughish. Stipula elongated.—Very general in meadows and pastures throughout Europe, particularly where the soil is moist, flowering from June to September, and forming perennial tufts of valuable herbage for the food of domestic cattle. The *stems* are a foot and half high, rough when drawn through the hand, by which this species is known from the equally common and useful *P. pratensis*. The *leaves* are grass-green, pliant, with sheaths of their own length, crowned with an oblong pointed *stipula*. *Panicle* ample and spreading. *Florets* with five strong ribs, wanting in many of the last described. The web which connects them is copious and long. *P. setacea* of Hudson's first edition is a mere variety, with narrow involute leaves.

P. pratensis. Smooth-stalked Meadow-grass. Linn. Sp. Pl. 99. Willd. n. 8. Ait. n. 9. Curt. Lond. fasc. 2. t. 5. Knapp. t. 55. Engl. Bot. t. 1073.—Panicle spreading. Spikelets four-flowered. Glumes lanceolate, five-ribbed, connected by a web, stem smooth. Stipula short and blunt.—Equally common with the last, but it will grow in much drier situations. It flowers rather earlier, comes sooner into leaf, but Mr. Curtis remarks that the *trivialis* produces a better crop as the season advances. That ex-

cellent observer found the smoothness of the *stem* the best criterion for distinguishing this from the last; which Hudson and Ehrhart have likewise noted. The *panicle* of the present species is most inclined to assume a purple hue; and the web connecting the *florets* is peculiarly long and complicated. *P. angustifolia*, Linn. Sp. Pl. 99, is a trifling variety, whose lower *leaves* are narrower and more rigid, with roughish sheaths, and the *panicle* is smaller. This variety is figured in Leers, t. 6. f. 3.

P. humilis. Short Blueish Meadow-grass. Ehrh. Calam. n. 115. Sm. Fl. Brit. 1387. Ait. n. 10. (*P. subcærulea*; Engl. Bot. t. 1004. *P. cærulea*; Knapp. t. 118.)—Glaucous. Panicle spreading. Spikelets ovate, of about three acute florets, connected by a web. Stipula very short and blunt.—Native of mountainous pastures in Westmoreland, Cumberland, and Anglesea, flowering in June. *Root* perennial, creeping, with villous fibres. *Stem* from four to six inches high. Whole plant glaucous. *Florets* ribbed, green at the base, purple and brown in the middle, white and membranous at the margin. Schrader, who directs us to strike out the synonyms of Willdenow, Haller, and Scheuchzer, quoted in Fl. Brit. (as belonging to his *supina*, Fl. Germ. v. 1. 289.) thinks the present plant differs from *pratensis* in its glaucous colour only. We agree that this is the chief distinction, but it seems to us essential. Hudson made our plant a variety of *pratensis*, but he mistook it for the Linnæan *alpina*, a widely different species.

P. annua. Annual Meadow-grass. Linn. Sp. Pl. 99. Willd. n. 16. Ait. n. 11. Curt. Lond. fasc. 1. t. 6. Mart. Rust. t. 98. Engl. Bot. t. 1141. Knapp. t. 52.—Panicle widely spreading. Spikelets ovate. Florets a little remote, five-ribbed, destitute of a web. Stem oblique, compressed.—Common every where in waste as well as cultivated ground throughout Europe, flowering at all times of the year when the weather is mild. In gardens it is a troublesome weed; in pastures it affords excellent food for cattle, and is rather improved than damaged by being trodden. Though the *roots* are annual, the lower part of the *stems* spread by numerous fibres, and thus the plant extends itself widely during summer, as well as by scattering abundance of seed. The herbage is bright green, not glaucous. *Leaves* flat, with a crumpled appearance here and there. *Sheaths* compressed, crowned with a sharp *stipula*. *Spikelets* ovate, variegated with green and white, rarely reddish. *Florets* a little silky at the back, membranous at the edge, destitute of a web at their base.

P. glauca. Slender Glaucous Meadow-grass. Fl. Dan. t. 964. With. 148. Sm. Fl. Brit. 1388. Engl. Bot. t. 1720. Ait. n. 19. (*P. casia*; Knapp. t. 56. P. n. 1468; Hall. Hist. v. 2. 224. *Festuca airoides*; Lamarck Dict. v. 2. 464, excluding the reference to Haller's n. 1439, which is *Festuca pumila* of Willd. Sp. Pl. v. 1. 420.)—Panicle glaucous, slender, erect. Spikelets ovate, of about three flowers. Glumes bluntnish, silky-edged, unconnected by any web. Stipula very short.—Found on the loftiest mountains of Wales and Scotland; perennial, flowering in June. The whole plant is very glaucous, and of a much more slender habit than any of the foregoing, in which last character it approaches the following. Schrader indeed suspects it to be but a mountain variety of the *memoralis*. The *spikelets* however are more ovate and close, and we believe the glaucous colour to be an important distinction. If however the proximity of this, in other respects, to *memoralis*, and of our *humilis* to *pratensis*, should be thought to invalidate that character, we submit our opinion to the test of cultivation by seed, which alone can decide the question.

P. nemoralis. Wood Meadow-grass. Linn. Sp. Pl. 102. Willd.

Willd. n. 47. Ait. n. 20. Engl. Bot. t. 1265. Knapp. t. 58. Fl. Dan. t. 749. Hofst. Gram. Austr. v. 2. 51. t. 71. —Panicle and leaves slender. Spikelets lanceolate, of about three flowers. Glumes acute, obsoletely five-ribbed. Stipula very short, notched.—This grass composes the tall thin herbage in woods or groves in the north of England, as well as rather mountainous woods throughout Europe. In lowlands it is less frequent, except on chalk. It is perennial, flowering in July and August. The whole plant is extremely slender, grass-green, one and a half, or two feet high. Stems smooth, flattish. Leaves rough to the touch, taper-pointed. Sheaths smooth, tight, compressed, shorter than the leaves. Stipula very short, notched, or torn. Panicle nearly erect, loose, capillary, zigzag, rough. Spikelets small, pale green, lanceolate rather than ovate. Glumes rough at the keel. Florets from two to four, shining, lanceolate, silky at their backs and hairy at the base, but not connected by a web.

There is a flouter variety, Hudson's *P. angustifolia* α , the true *nemoralis* being his β .

P. decumbens. Decumbent Meadow-grass. Scop. Carn. v. 1. 69. With. 147. Sm. Fl. Brit. 107. Ait. n. 24. Schrad. Germ. v. 1. 305. Engl. Bot. t. 792. Knapp. t. 59. Hofst. Gram. Austr. v. 2. 52. t. 72. (*Festuca decumbens*; Linn. Sp. Pl. 110. Willd. Sp. Pl. v. 1. 424. Fl. Dan. t. 162.)—Panicle nearly simple, condensed, erect. Spikelets ovate, of four florets, scarcely exceeding the calyx. Stipula briefly.—Native of spongy bogs, in barren sandy or mountainous situations, flowering in July. This species is perennial, of a remarkably harsh and rigid habit, lying close to the ground, except when in flower, and of no agricultural use. The roots creep moderately, and are very strong. Stems about a foot long. Leaves straight, tapering, acute, rather glaucous, with long hairy sheaths, and a brittle tuft of hairs in the place of the usual membranous stipula. Panicle zigzag, of a very few large purplish-glaucous flowers, of so ambiguous an appearance, that botanists have differed much about the genus of the grass in question; some making it a *Melica*, to which, as Linnæus remarks, it has a degree of affinity in habit as well as structure. Koeler esteems it a *Bromus*, and Bernhadi, like Decandolle, cuts the knot, by making it a new genus, we know not by what essential character. Mr. Brown is inclined to refer this puzzling plant to his own *Triodia*, Prodr. Nov. Holl. v. 1. 182.

The extra-european species of *Poa* afford a wide range for the botanist, too extensive for our present purpose. They require a more general investigation than they have yet received, though abundance of particular species have been described with sufficient care. Those of American growth agree best, as might be expected, with our's. Some tropical ones have so different an aspect, that it is to be wished they possessed some generic distinction. Many of them are singularly elegant when minutely examined. We apprehend that a great number still remain undescribed.

POA, in *Agriculture*, a genus of grasses, which principally forms the green covering of the fields: the meadow-grass.

There are several species, some of which are highly useful as field-grasses.

Poa Angustifolia, the narrow-leaved meadow-grass, which Mr. Sole says is a very sweet grass, especially for hay, but like the *trivialis*, is liable to go off after mowing. It is dispersed sparingly in the meadows about Hinton Abbey.

Poa Annua, the dwarf or white meadow, or Suffolk grass, which, according to Mr. Sole, is the quickest in growth of all the grasses, coming up, blooming, and ripen-

ing its seeds in the course of one month. It ought therefore to be called *mensual*; but as it will keep time with no other grass, it is not worth sowing. It is always leaving the ground bare in patches, except there happens to be an *agrostis* to fill its place. It is however a very sweet grass, and very generally liked by animals of most sorts.

Poa Aquatica, the reed meadow-grass, which Mr. Sole says, is an excellent grass in its native soil, the fens of the isle of Ely, growing to the height of six feet. It is usually cut when about four feet in height, and when dry, is bound into sheaves; and it mostly undergoes a heat in the stack that improves its quality. It is found an excellent fodder for milch cows, but horses are not fond of it. In that place it is called *fodder* by way of eminence, other sorts of coarse hay being denominated *stover*, which signifies *coarse stuff*, and it is called *white lead*, from its drying of a white colour.

Poa Bulbosa, the bulbous meadow-grass, which Mr. Sole finds to have all the good qualities of the *pratensis*, in so far as its size will admit, and it is proper for hilly dry grounds and poor soils, where it delights to grow. It is found in the hilly dry pastures about Newton St. Loe.

Poa Compressa, the compressed, or flat stalked meadow-grass, which Mr. Sole thinks an excellent grass for parks and sheep-walks, as both deer and sheep are fond of it; and as it is a dwarf grass, the blades seldom exceeding two inches in height, it forms a fine turf, and causes the flesh of the animal to cut short, and be fine flavoured. It is found in blossom in some places about Claverdon Down, and probably on the down itself, but the sheep there never suffer a bent of it to blow.

Poa Difflans, the fen meadow-grass, which Mr. Sole finds an exceedingly sweet grass, affording very rich milk, but it is difficult to cultivate, as it delights in miry situations. It grows in most sea-marshes, and abundantly about Cottenham, and the fens of Cambridgehire.

Poa Loliacea, the hard or darnel meadow-grass, which Mr. Sole thinks the most insignificant of all the poas, but which has one good property, that of growing where no other grass is capable of living, as in the driest parching sea-fands.

Poa Maritima, the sea meadow-grass, which the same botanist considers as a fine nourishing grass, being the principal one of our best salt-marshes; but from its delighting in salt, is difficult of cultivation.

Poa Palustris, the marsh meadow-grass, which Mr. Sole thinks a fine exuberant grass, and probably the best dairy grass. It grows in the rich marshes in all parts of the island, particularly those that are frequently refreshed by the occasional overflowings of rivers. It is valuable for laying down spongy lands. It has often the height of four or five feet; and the panicle, when full blown, is extremely fine and flowing.

Poa Pratensis, the great or smooth-stalked meadow-grass, which, for the purposes of agriculture, is considered by Mr. Sole as the most noble of all the grasses. Its foliage begins to shoot and put on a fine verdure early in the spring, but not so soon as some other grasses. Every animal that eats grass is fond of it; while it makes the best hay, and affords the richest pasture. It abounds in the best meadows about Laycock and Chippenham, and it has the valuable quality of abiding in the same land, whilst most other grasses are continually changing. According to some, it delights in rather a dry than a moist soil and situation, on which account it keeps its verdure better than most others in dry seasons; but it thrives most luxuriantly in rich meadows. It has been objected to by some from its creeping roots, which are difficult to extirpate, of course it is probably the most suited

suiting to permanent grass lands. According to Curtis it is distinguished from the rough-stalked meadow-grass, by the stem being smooth when drawn between the finger and thumb, and while in that the membrane at the base of the leaf is long pointed, in this it is short and blunt. And besides, it only throws up flowering stems once in the season, and is of course well suited for lawns, &c.

POA Setacea, the fine meadow-grass, which Mr. Sole considers as a fine rich grass for upland pastures, as it delights in a dry soil. It is found in the hilly pastures about Newton, in Somersetshire. It is likewise an abiding grass.

POA Trivialis, the common or rough-stalked meadow-grass, which Mr. Sole thinks a fine grass for hay as well as pastures, but inferior to the pratensis. It delights in moisture and sheltered situations, on which account it is tender though productive. In rich land it grows tall; its height however is about two feet. It is said by some to be well suited to good found moist loams. It is much esteemed on the continent for dry pastures and watered meadows, as it multiplies by seed as well as the root. It is of course proper to let the seeds fall. Its fattening property is considerable for cattle. It is, however, apt to go off after mowing, being overpowered by those grasses of the bent kind. Its radical leaves, as well as those on the stem, grow much larger than in the pratensis. In sowing it the seeds should be carefully separated.

POAKE ROOT, in Virginia, is used to denote the *Solanum bacciferum*. The Indians use it for a purge, though commonly deemed a poison. Phil. Trans. N^o 454. § 1.

POBEDA, LA, in *Geography*, a town of Spain, in Old Castile; 13 miles N. of Soria.

POBETTEN, a town of Prussia, in the province of Samland; 16 miles N.W. of Königsberg.

POBIANITZA, a town of the duchy of Warfaw; 33 miles E.N.E. of Siradia.

POBINDEN, a town of Prussia, in the province of Samland; 15 miles N. of Königsberg.

POBLA, LA, a town of Spain, in Catalonia; 25 miles N.W. of Salfoa.

POBLA de Lillett, a town of Spain, in Catalonia; 20 miles E.S.E. of Urgel.

POBLACION, a town of Spain, in Navarre; 12 miles W. of Estella.

POBLEDA, LA, a town of Spain, in Old Castile; 21 miles S.W. of Calahorra.

POBNITZ, a river of Bohemia, which rises near Culmbach, on the borders of Silesia, and runs into the Elbe, near Tetschen.

POCAHONTAS, a town of Chesterfield county, in Virginia, within the jurisdiction of Peterburg, in Dinwiddie county; probably deriving its name from the famous princess Pocahontas, the daughter of king Powhatan. Morfe.

POCAR, a town of Naples, in Principato Citra; 7 miles W. of Salerno.

POCATSJETTI, H. M., in *Botany*, the name of a small shrub which grows in Malabar. The leaves powdered and sprinkled upon ulcers, repels luxuriant and fungous flesh; and taken internally, they excite a sweat, and diminish the paroxysm of an intermitting fever.

Of the bark and root, powdered, and mixed with oil, an unguent is made, said to be good for the itch, and other cutaneous disorders.

POCCOON. See **Puccoon**.

POCHARD, in *Ornithology*, the name of a species of wild duck, called by some the *penelope* and *rotbhals*, and by many in English the red-headed widgeon.

It is larger than the common widgeon, and is shorter and

thicker bodied. This is the *ANAS ferina* of Gmelin. See **Duck**.

POCHERRY, in *Geography*, a town of Hindooftan, in Marawar; 5 miles S. of Ramanadporum.

POCK. See **Pox**.

POCK-Wood. See **GUAIACUM**.

POCKESO, in *Geography*, a populous and commercial town of Africa, in the district of Axim, on the Gold Coast.

POCKET SHERIFFS, in *Law*, sheriffs nominated of the sole authority of the crown. See **SHERIFF**.

POCKET, in *Rural Economy*, a large sort of bag, in which hops are packed up, in order to be sold; being formed of a particular kind or quality of lacking. See **HOPS**.

POCKET of Wool, is half a sack. See **SACK of Wool**.

The pocket contains usually twenty-five hundred weight of wool.

POCKET Instruments, in *Surgery*, are such as a surgeon ought always to have in readiness, and may conveniently carry about him in a proper case: these are two lancets of different sizes; the one proper to open abscesses, the other smaller, for bleeding; a pair of straight scissars, useful on many occasions; a pair of crooked scissars, proper to be used in dividing fistulæ, and in several other cases; a pair of forceps, with teeth at one end, to remove dressings, and upon occasion to extract splinters or thorns: these are also serviceable to the surgeon in his anatomical exercises; they are commonly made of steel, but those of silver are much neater; a razor; a straight incision-knife; a crooked incision-knife; a straight double-edged incision-knife; a probe with one end broad and thin, proper for discovering a fissure in the cranium, and for many other uses; and the other end rounded, to examine the depth and situation of wounds and ulcers. The neatest probes are made of silver, though they are frequently made also of steel, ivory, or whalebone; a grooved probe or director, to direct the edge of the knife or scissars in opening sinuses, or fistulæ, that by this means the subjacent vessels, nerves, and tendons, may remain unhurt. The upper end of this instrument sometimes is ornamented, and serves only for a handle; sometimes it is made in form of a spoon, to contain powder to sprinkle upon wounds or ulcers; sometimes also this is made forked at the end, to divide the frænum of the tongue; a spatula to depress the tongue, in order to examine the state of the tonsils, uvula, and fauces, when they are affected with any disorders; it is also used to suspend the tongue when the frænum is to be divided; for which purpose it is to be made with a fissure at its extremity, and should therefore rather be made of silver than of any other metal. Besides these, there should be an ordinary spatula for spreading plasters, ointments, and cataplasms; and sometimes, by means of their sulcated extremity, they are of service in raising up fractured bones of the cranium; several needles mult also be kept here, some straight and others crooked, for the stitching up of wounds, taking up of arteries, and many other uses. Heister's Surg. p. 12.

POCKET Medicines. See **MEDICINE**.

POCKLINGTON, in *Geography*, is a market town and parish, situated partly within the liberty of St. Peter, York, and partly in Wilton-Beacon division, in the wapentake of Harthill, East Riding of Yorkshire. The town is distant from York 13 miles E. by S., and from London 197 N. by W. The market-day is Saturday every week, and there are four fairs annually. Here are held the petty sessions for Wilton-Beacon division of the wapentake of Harthill. The living is a vicarage in the patronage of the dean of York. According to the parliamentary returns of 1811, the houses

houses in this town were estimated at 396, and the inhabitants at 1539 in number.

Several places in the vicinity of Pocklington merit the notice of the topographer and antiquary. The Roman road, called the Ermine-street, passes within two miles to the west of the town. Londeborough-park, which it intersects at the distance of three miles, is supposed by Drake, the historian of Yorkshire, to be the ancient Delgovitia, but the circumstances upon which he founds his opinion are by no means conclusive. This place was for many centuries a seat of the ancient and celebrated family of the Cliffords. It is now the property of the duke of Devonshire, as descendant from the daughter and heiress of Henry Clifford, the fifth and last earl of Cumberland. The house is situated on elevated ground, and is surrounded by an extensive and well wooded park. At Melburn, five miles to the south-west of Pocklington, is the seat of sir Henry Vafavour, bart. The mansion is a large modern edifice of brick, and commands some fine views of the western acclivities of the wolds. Stamford-bridge, eight miles to the north-west, Drake conceives to be the scite of the Derwentio, but Camden fixes that station at Aldby, about a mile and a half to the northward. Here was fought, in 1066, one of the most bloody battles recorded in the history of England, between the forces of Harold II. and those of Tofti his brother, the banished earl of Northumberland, assisted by Harfagar, king of Norway. The contest lasted from seven in the morning till three in the afternoon, when the Norwegians and rebels were routed with immense slaughter. Beauties of England and Wales, vol. xvi. by John Bigland.

POCKREKESKO, a river of North America, in New-Britain.

POCO ALLEGRO, in the *Italian Music*, is not so fast as allegro.

Poco Largo, intimates to play or sing a little slow. See LARGO.

Poco meno Allegro, is used to signify that the part it is joined to should be played or sung in a little less gay manner than allegro requires.

Poco Presto, serves to let us know that we ought to sing or play that part to which it is annexed, not quite so quick as presto requires it should.

POCOCK'S ISLAND, in *Geography*, an island in the East Indian sea, S. lat. 6° 2'. E. long. 118° 12'.

POCOCKE, EDWARD, in *Biography*, a celebrated orientalist, was born at Oxford in 1604: he received the early part of his education at the free school of Tame, and in 1618 was entered a commoner of Magdalen Hall, Oxford. In 1620 he removed to Corpus Christi college, in which he obtained a scholarship. He now began to apply himself to the study of the oriental languages, and the ardour which he manifested in the pursuit, caused him to make extraordinary progress in a comparatively short time. In 1627 he began to prepare, from a MS. in the Bodleian library, a Syriac version of four epistles, which were yet wanting to a complete translation of the New Testament into that language. This work he finished in 1628, and in the same year he was admitted probationary fellow of his college; and the epistles coming to the knowledge of Gerard John Vossius, he carried them to Leyden, where they were printed under the inspection of Lewis de Dieu. Pococke was ordained priest in that year; and having been appointed chaplain to the English factory in Aleppo, he arrived at that city in 1630. He instantly took advantage of the situation; engaged a master in the Arabic tongue, and a servant of the nation for the purpose of familiar converse in it. As a still surer guide, he undertook the translations of several

Arabic books, among which was a collection of 6000 proverbs. Having received a commission from the famous Dr. Laud, bishop of London, for the purchase of Greek coins, and Greek and Oriental MSS., he was eager in obtaining them; though more than once the zeal which he shewed for his employer exposed him to imminent danger from the plague. In 1636 he was nominated by the bishop first professor of the Arabic lecture founded by that munificent prelate at Oxford. He accordingly returned to take possession, and in August of the same year he opened his lectures with an eloquent Latin oration, on the nature and use of the Arabic tongue. Having commenced his official duties, he obtained leave of absence to embark with a learned mathematician, in 1637, for Constantinople. Here he staid till 1640, and passing through Paris on his return, he had an interview with the illustrious Grotius, who was much gratified on being consulted by him on the Arabic translation of his celebrated work, "De veritate Christianæ Religionis."

On his arrival in England, he had the mortification and misery to find his patron, bishop Laud, a prisoner in the Tower. In 1643 he was presented by his college to the rectory of Childrey, in Berkshire, and he immediately set himself to perform the functions of a parish priest, with all the modesty and simplicity of his character. In the following year, the salary of his professorship being seized by the sequestrators as part of the archbishop's estate, Pococke was reduced to his country living. He thought it now suitable to his situation to marry, and in 1646 he formed an union with the daughter of Thomas Burdett, esq. of Hampshire. Soon after this, by the interest of the learned Selden, he obtained the restoration of his salary, and was at the same time completely protected from the violences of the soldiery. In 1648, the Hebrew professorship at Oxford, with the prebend of Christ-church annexed, was given to him; but as he steadily refused to subscribe the engagement, he was not deemed eligible. Attempts were made to deprive him of his prebend and both his professorships; the former he actually lost, but by the intercession of powerful friends, he was allowed to retain the latter. In 1650 he published his "Specimen Historiæ Arabum," and in 1652 he engaged to afford his assistance to the editors of the Polyglott Bible, his task being the collation of the Arabic pentateuch. In 1654 he was in danger of being ejected from his living on account of ignorance and insufficiency; at least those were the charges preferred against him by Cromwell's committee. Some of his Oxford friends, however, particularly Dr. John Owen, so warmly represented the disgrace which would follow the rejection upon such grounds, of a man more eminent than almost any other in Europe for sound learning, that the prosecution was abandoned. In 1655 he published "Porta Mosis," being six prefatory discourses of Moses Maimonides, containing an account of the Jewish doctrine and discipline. Mr. Pococke added a Latin version, with a large appendix of miscellaneous notes, and this was the first specimen of the Hebrew press at Oxford. In 1659 he published, according to his promise made to Selden, the annals of the patriarch Eutychius, in Arabic and Latin, with Selden's preface and notes. On the restoration of Charles II. he obtained the restitution of his prebend and canonry of Christ-church, and in that year, 1660, he took his degree of D.D. He had the mortification to find, that in the new reign oriental literature fell into discouragement, nevertheless he continued through life to perform the duties of his professorships. His other publications after this were "Carmen Abu Ismaelis Togræi," Arab. et Lat.: "Gregorii Abul Farajii Historia Dynastiarum," Arab. et Lat.: "Commentaries upon Micah, Malachi, Hosea, and Joel;" in these he is a defender of the purity of

of the Hebrew text against the objections of several learned men, and he takes great pains to set in a strong light the predictions of the Old Testament, generally supposed by Christians to relate to Jesus Christ. The last of these he published in 1691; and if he intended, which is not certain, to pursue the same plan with the other minor prophets, he was prevented therein by his death, which happened on the 10th of September, in that year, being in the 87th year of his age. A gradual diminution of strength and bodily vigour had for some time, previously to this, indicated his approaching dissolution, but his intellects and memory were continued almost unimpaired to the last. His body was interred in the cathedral of Christ-church, and on the north wall there is a monument, with an inscription, from which the following is an extract, "Edwardus Pococke, S.T.D. cujus nomen audias, nihil hic defama desideres." To the excellence of his private character, Mr. Locke bears the most ample testimony. He represents him as free, open, and intelligent in his conversation; sincere, modest, humble, and tranquil, singularly charitable, and forgetful of injuries. He adds, "his life appeared to me one constant calm. To conclude, I can say of him what few men can say of any friend of theirs, nor I of any other of my acquaintance; that I do not remember I ever once saw in him one action, that I did, or could in my own mind blame, or thought amiss in him."

As a scholar, his knowledge of language comprised all the principal oriental tongues, with some European, besides the Latin and Greek. He was father of a numerous family, of whom the eldest son, Edward Pococke, published under his father's direction, in 1671, an Arabic work, with a Latin version, entitled "Philosophus Autodidactus, five Epistola Abu Jaafir Ebn Tophail de Hai Ebn Yokdhan." The design of the author Abu Jaafir Abn Tophail, who was a Mahometan philosopher, is to shew, by an ingenious fiction, how human reason, by observation and experience, without any assistance, may arrive at the knowledge of natural things, and from thence rise to supernatural, particularly to God and a future state. For this purpose he supposes a person, Hai Ebn Yokdhan, brought up by himself, where he was altogether destitute of instruction, but what he could get from his own observations. Mr. Pococke had also prepared an Arabic history, with a Latin version, and actually sent it to the press; but this performance, not being worked off when his father died, was withdrawn by him upon a disgust at his being disappointed of succeeding him in the Hebrew professorship. Biog. Brit.

POCOCKE, RICHARD, a distinguished traveller, and a prelate of the Irish church, son of a clergyman of Southampton, was born in 1704. He was educated at his native place, whence he was removed to Corpus-Christi college, in Oxford. In 1731 he took the degree of bachelor of laws, and in 1733 that of doctor. About this time he made a tour on the continent, probably as tutor to some young man of rank. In 1736 he made a second tour, in which he took his course through Holland, Germany, Hungary, and Italy, to Leghorn. In 1737 he embarked for Egypt, in which country he pursued his travels till the following spring. In the month of March, 1738, he embarked at Damietta for Palestine, and then took his road through Syria, Mesopotamia, Cyprus, Candia, and Lesser Asia, to Constantinople. He returned by sea from Cephalonia to Messina, whence, through Italy, Germany, and Flanders, he proceeded homewards. He returned in 1741, having been absent five years. The results of his observations and researches were given to the public, under the title of "Description of the East, and some other Countries," of which the first volume, entitled "Observations on Egypt," dedicated to Henry, earl of

Pembroke and Montgomery, appeared at London in 1743; and the second, entitled "Observations on Palestine, Syria, Mesopotamia, Cyprus, and Candia," dedicated to Philip, earl of Chesterfield, in 1745. These publications were well received: his remarks chiefly relate to buildings, inscriptions, and other remains of antiquity, but he has likewise many observations respecting manners and customs, and the products of nature and art, in the countries which he visited.

When the earl of Chesterfield was appointed lord-lieutenant of Ireland, in 1745, he carried Dr. Pococke with him as one of his domestic chaplains, and he soon appointed him archdeacon of Dublin. In 1756, the duke of Devonshire, then lord-lieutenant, promoted him to the bishopric of Ossory. He was translated to Meath in 1765, in which he died. Dr. Pococke, besides being an Oriental traveller, made a tour in Scotland, and gave a description of the basaltic rock in the harbour of Dunbar, resembling the Giant's causeway, which was printed in the Philos. Transf. vol. 32; also of some antiquities found in Ireland, printed in the second vol. of the Archæologia, vol. ii. Several MSS. which he presented to the British Museum, are preserved in that repository. Pococke's Travels.

POCOGNACA, in *Geography*, a town of Italy, in the department of the Mincio; four miles N. of Mantua.

POCOKOLIGO, a village of South Carolina; 15 miles from Combabec ferry, and 67 from Charleston.

POCOMOCK, a river of the state of Maryland, which discharges itself into the Chesapeake bay, forming a large bay at its mouth, called "Pocomock bay." N. lat. 37° 50'. W. long. 75° 50'.

POCONA, a town of Peru; 60 miles S. of Cuzco.

POCUMMA, in *Botany*, a name given by the people of Guinea to a species of plant which they use as an astringent. Their manner of taking it is very singular; for they put the leaves among their dough, and bake them into a mass with the bread, and then eat the whole together in their food. Phil. Transf. N° 232.

POCUTIA, or POKUCIA, in *Geography*, a province of Poland, annexed to Aultria, and included in the kingdom of Galicia.

POD, in *Botany* and *Vegetable Physiology*, has been considered as synonymous with the Latin *legumen*, as well as with *siliqua*; but it is now restricted to the latter, *legume* being used for the former. See LEGUME and SILIQUA.

PODAGRA, ποδαγρα, thus called from πους, foot, and αγρα, captura, seizure, in *Medicine*, the gout in the feet.

PODAGRA *Dentium*, sometimes, though with impropriety enough, is used for the tooth-ach.

PODAGRA *Lini*; in *Botany*, a name given by some of the later Greek writers to cuscuta, or dodder, when found growing on the linum of flax. The Latins have called this *epilinum*, as they do the dodder growing on thyme *epithymum*; the earlier Greeks called this *linoxystes*. Where this dodder takes root in a field of flax, it generally occupies many plants; and where it twines round them it causes protuberances and swelling, and has therefore been resembled to the gout on that plant.

PODAGRARIA, a name given by many authors to the lesser wild angelica, called alio *herba Gerardis*.

PODALA, in *Geography*, a town of Hindoostan, in the Carnatic; 18 miles W. of Ongole.

PODALIRIUS, in *Biography*, an illustrious physician, and reputed son of Æsculapius, is celebrated by Homer as having accompanied the Grecian army in the Trojan war, together with his brother Machaon. He appears to have been the younger brother, and to have been on the whole less distinguished

distinguished than Machaon; though, like him, he was married to the daughter of a king. On his return from the siege of Troy, he was shipwrecked on the coast of Caria, where he was hospitably received by a shepherd, who, having learned that he was a physician, took him to king Damæthus, whose daughter had accidentally fallen from the top of a house. Podalirius bled her in both arms, after which she recovered, which so delighted the king, that he gave him his daughter in marriage, with the Cherfones as a portion. Here Podalirius built two cities, the one of which he called Syrnium, from his wife, Syrna, and the other Bybassus, which was the name of the shepherd who had received him when shipwrecked. Among other children, he had a son, called Hippolochus, from whom, in a direct line, Hippocrates considered himself as descended. See Le Clerc. Hist. de la Médecine, p. i. chap. 18. See MACHAON.

PODALYRIA, in Botany, a well-sounding name, which seems its chief recommendation; for we do not perceive what title the brother of Machaon, however famous a physician, has to botanical honours. The etymology of the original seems to be ποδάλυριος, lily-footed. The Hindoos at this day use *lotus-footed* as a compliment.—Lamarck Illustr. t. 327. f. 3, 4. Willd. Sp. Pl. v. 2. 501. Ait. Hort. Kew. v. 3. 6.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, short, bell-shaped, in five unequal segments; its base externally concave. Cor. papilionaceous, of five petals. Standard twice as large as the rest, kidney-shaped, with a thick claw. Wings two, shorter than the standard, half-obovate, converging at their upper edges. Keel shorter than the wings, and covered by them, of two oblong converging petals. Stam. Filaments ten, awl-shaped, ascending, equal, inserted into the base of the calyx, permanent, cohering at the bottom; anthers roundish, small. Pist. Germen sessile, ovate; style longer than the stamens, ascending; stigma simple, obtuse. Peric. Legume ovate, turgid, coriaceous, of one cell. Seeds several, kidney-shaped.

Ess. Ch. Calyx in five unequal segments; hollow externally at the base. Corolla papilionaceous; the standard largest. Stamens permanent, combined at the base. Legume inflated, with many seeds.

This genus is limited by Mr. Salisbury and Mr. Brown to the simple-leaved species of Lamarck and Willdenow, to which only the above characters apply. They are shrubs, natives of the Cape of Good Hope, with a very silky habit, and confounded by Linnæus and Thunberg under *Sophora*. The ternate-leaved species of Lamarck and Willdenow compose the *Baptisia* of Ventenat, and Hort. Kew.; for those with pinnate foliage, see VIRGILIA.

1. *P. myrtilifolia*. Bilberry-leaved Podalyria. Willd. n. 13. Ait. n. 1. (Genista arborefcens africana, styracis folio, flore cæruleo; Herm. Lugd.-Bat. 270. t. 271.)—"Leaves oblong-obovate, silky on both sides. Calyx silky. Stalks single-flowered, nearly as long as the leaves."—A greenhouse plant, flowering from April to July, introduced at Kew in 1795, but cultivated at Leyden more than a century earlier. Hermann says it grows at the Cape, in watery places. The stem is bushy, with hoary branches. Leaves numerous, alternate, coriaceous, rather pointed, clothed on both sides with white silky down. Flowers axillary, generally solitary, blueish. The specific name is not happy.

2. *P. sericea*. Silky Podalyria. Ait. n. 2. (*Sophora sericea*; Andr. Repof. t. 440.)—"Leaves oblong-obovate, silky on both sides. Calyx silky. Stalks single-flowered, many times shorter than the leaves."—Found at the Cape

by Mr. David Nelson, and introduced into Kew garden in 1778. It flowers from August to November, but rarely. This has more considerable recurved points to the leaves, and pale purplish flowers, supported by short, simple, foliary, axillary stalks. The legume is an inch long, very silky, like every other part, except the corolla.

3. *P. biflora*. Two-flowered Podalyria. Lamarck f. 3. Willd. n. 12. Ait. n. 3. Curt. Mag. t. 753. (*P. argentea*; Salif. Parad. t. 7.)—Leaves oval, pointed, silky on both sides. Calyx clothed with dense rigid down. Stalks two-flowered, much longer than the leaves.—Native of the same country. Mr. Masson sent it to Kew in 1789. It flowers in May and June, and occasionally at other seasons. The leaves are rather less decidedly obovate than in the two former. Flower-stalks stout, twice or thrice as long as the leaves, each bearing two, rarely three, large, handsome, sweet-scented, white or pale purplish flowers, whose calyx is of a rusty hue, rough with rigid short down, that is most dense in the wild specimens. Linnæus doubtless comprehended this plant under his *Sophora biflora*, but he confounded with it two or three others, so that he cannot, with precision, be quoted for any.

4. *P. calyptata*. Reticulated Podalyria. Willd. n. 11. Ait. n. 4. (*Sophora calyptata*; Retz. Obs. fasc. 1. 36. Crotalaria; Seb. Mus. v. 2. t. 99. f. 3, good. Willd.)—Leaves somewhat obovate, reticulated beneath; downy when young. Stalks single-flowered, about equal to the leaves. Calyx villous; its limb membranous, reflexed.—From the same country; sent to Kew in 1792. It flowers during summer. The smoothness of the adult leaves, and their strong copious reticulations beneath, mark this species at first sight. The stalks, shorter than the last, bear but one flower, accompanied, as in the rest, by a deciduous bractea. Corolla purplish.

5. *P. hirsuta*. Hairy Podalyria. Willd. n. 14. Ait. n. 5. (*P. styracifolia*; Sims in Curt. Mag. t. 1580?)—"Leaves villous, stalked; the upper ones ovate; the lower roundish. Stalks single-flowered. Calyx villous; its segments the length of the wings."—Sent by Mr. Masson from the Cape, in 1774. The flowers are more copious than in any of the former, but not of frequent occurrence. Leaves in our wild specimen nearly orbicular; the adult ones almost smooth above. Flower-stalks about the length of the leaves. Corolla pink, large and handsome. The foliage in the Botanical Magazine is drawn more ovate than we have seen it, but answers the better to Mr. Brown's specific character given above, and we are therefore more inclined to refer Dr. Sims's plant to the present than to the last species. He speaks of it as a beautiful shrub, requiring an airy greenhouse, propagated by cuttings, and blooming from May to July. No wonder that it has passed unexamined, under the name of *biflora*, as it so rarely produces flowers. Linnæus applied that name to a specimen of this, pasted with one of the *calyptata*, on the same paper.

6. *P. buxifolia*. Box-leaved Podalyria. Willd. n. 15. (*Podalyria*; Lamarck f. 4. *Sophora buxifolia*; Retz. Obs. fasc. 1. 35. *S. pedunculata*; Thunb. Prodr. 79.)—Leaves elliptic-obovate; smooth above; silky beneath. Stalks single-flowered, longer than the leaves. Calyx downy, coloured, acute.—Native of the Cape, but not yet known in our greenhouses. We have seen no specimen. The leaves are represented about the size and shape of Box, scarcely half, or one-third, the length of the flower-stalks; but Retzius describes the latter as no longer than the leaves. The calyx is hairy within, as well as without; its segments acute. Corolla purplish, with paler wings.

7. *P. cordata*. Heart-leaved Podalyria. Ait. n. 6. (Sophora

(*Sophora cordata*; Thunb. Prodr. 79? *Brown*.)—"Leaves heart-shaped, roundish, nearly sessile, extremely villous. Stalks two-flowered. Calyx villous, its segments shorter than the wings. Sent by Mr. Maffon from the Cape to Kew, in 1794. It flowers there from May to July. We have seen neither specimen nor figure. Willdenow omitted Thunberg's plant, because the character was not sufficient to satisfy him respecting it.

Lamarck represents, at his fig. 5, another supposed species; a small shrub, with inversely heart-shaped leaves, and solitary, nearly sessile, flowers; the legume small, ovate, hairy, single-seeded. This seems unnoticed by any subsequent writer, nor are we acquainted with the plant.

PODANA, in *Geography*, a town of Hindoostan, in the circar of Condapilly; eight miles from Masulipatam.

PODANG-MEW, a large and populous city of the Birman empire, not far from the city of Prome.

PODARIA, in the *History of Insects*, a classical name comprehending all such insects as have limbs, but no wings. Hill. See *APTERA*.

Of this class there are two subdivisions. 1. Such *aptera podaria* as have oblong bodies with numerous legs, or more than six pair: these are the julus, or gally-worm; the scolopendra, or centipes; and the oniscus, or wood-louse. 2. The *aptera podaria* with shorter bodies, and less numerous legs, or fewer than six pair. This subdivision contains numerous genera, as the pulex; the podura or puceon, the pediculi of various kinds, the monoculi, the acari, the aranei, the scorpio, and a great many others. See *GALLY-Worm*, *SCOLOPENDRA*, &c.

PODEM, in *Geography*, a town of Asiatic Turkey, in the government of Trebizond; 30 miles E. of Trebizond.

PODEMNO, a town of Russia, in the government of Tobolsk; 44 miles E. of Kemikoi.

PODENDA, a town of Asiatic Turkey, in Aladulia, at the confluence of Seihoun with the Adana; 33 miles N. of Adana.

PODENSEE, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Bourdeaux; five miles N.W. of Cadillac. The place contains 1425, and the canton 15,688 inhabitants, on a territory of 250 kilometres, in 13 communes.

PODENSEE, a town of Austria; eight miles W. of Tulin.

PODENTES, a town of Portugal, in the province of Beira; 10 miles N.E. of Coimbra.

PODENZANA, a town of the duchy of Piacenza or Placentia; five miles S. of Piacenza.

PODERADOS, in *Ancient Geography*, an episcopal town of Phœnicia, the episcopate being dependent on Thebus, the second metropolis of the patriarchate of Antioch.

PODERIS, *ποδρίς*, from *πες*, pes, and *αψα*, apto, in *Antiquity*, a robe hanging down to the feet; but it is chiefly used to express a linen garment, a surplice, a shirt. The Jewish priests were covered with this kind of long surplices during the time of their attendance in the temple; and this was the proper habit of their order.

PODESTA, or POTESTA, a magistrate, or officer of justice and policy, in a free city.

The name is originally Italian, *podesta*; and is chiefly applied to certain magistrates of Venice and Genoa, whose function is to administer justice in those republics.

The podesta in Venice corresponds to the prator in ancient Rome, though appeals lie from his decisions to the new auditors, or the new civil quaranty. See *QUARANTIA*.

PODESTANA, in *Geography*, a town of Italy, in the Veronese; 15 miles N. of Verona.

PODETIUM, in *Botany*, from *πες*, a foot, a name appropriated by Acharius to the peculiar footstalk of the tubercles in the cup lichens. See *LICHENES*.

PODEX, in *Anatomy*, &c. the same with anus, or fundament.

PODGINOCK, in *Geography*, a town of Russia, in the province of Usting; 100 miles E.S.E. of Uit Sifolok.

PODGORODKOI, a fort of Russia, in the government of Upha, on the Ural; 92 miles E. of Orenburg.

PODGURZA, a town of the duchy of Warsaw, on the Viltula, opposite to Thorn.

PODHORSAN, a town of Bohemia, in the circle of Saatz; eight miles S.S.W. of Saatz. N. lat. 50° 12'. E. long. 13° 29'.

PODICEPS, in *Ornithology*, a name given by many to the several kinds of *colymbi*, or divers, as they are also called in English *arse-feets*; from their legs being placed very backward on their bodies, by which means they have great advantages in swimming and diving. See *COLYMBUS Podiceps*.

PODIEBRAD, in *Geography*, a town of Bohemia, in the circle of Koniggratz; 14 miles S.E. of Biezow.

PODISMUS, *ποδισμός*, among the Greeks, a certain space or number of feet laid out by surveyors; it was the same with what the Romans call *pedatura*.

PODIUM, in the *Theatre of the Ancients*, the wall that separated the orchestra from the scene. Mem. de l'Acad. vol. i. p. 190.

PODKAMIEN, in *Geography*, a town of Austrian Poland, in Galicia; 56 miles E. of Lemberg.

PODKAMNEN, a town of Russia, in the government of Tobolsk, on the Tchulim; 32 miles N. of Atchinsk.

PODLACHIA, a county or palatinate of Poland; bounded on the N. by Prussia and Lithuania, on the E. by Lithuania, on the S. by the palatinate of Lublin, and on the W. by Masovia; annexed by the conquest of Poland in 1596. It is also called the "Palatinate of Bielsk," from its capital.

PODMASCHESCHNAIA, a town of Russia, in the government of Archangel; 48 miles S.W. of Mezen.

PODOK, a town of Poland, in the palatinate of Braclaw; 30 miles N.W. of Braclaw.

PODOL, a town of Bohemia, in the circle of Chrudim; five miles W.S.W. of Chrudim.

PODOLEPIS, in *Botany*, aptly so named by Labillardiere, from *πες*, a foot, and *λεπις*, a scale, in allusion to the numerous scales, which clothe the flower-stalks.—Labill. Nov. Holl. v. 2. 56. Brown in Ait. Hort. Kew. v. 5. 82. (Scalia; Sims in Curt. Mag. v. 24. 956; a name adopted from Theophrastus, whose *ποδίζης* appears to belong to the same tribe.)—Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ capitatae*, Linn. *Corymbifera*, Juil.

Gen. Ch. *Common Calyx* hemispherical, imbricated, with numerous stalked membranous scales. *Cor.* compound, radiated. Florets of the disk numerous, tubular, all perfect, with five equal spreading segments; those of the radius female, ligulate, with from two to four oblong segments. *Stam.* Filaments, in the florets of the disk only, five, capillary; anthers united into a rather prominent tube. *Pistl.* in all the florets, German inferior, obovate; style cylindrical, scarcely so long as the stamens; stigmas two, bluntish, spreading. *Peric.* none, except the permanent calyx. *Seeds* solitary, oblong, compressed. *Down* sessile, capillary, roughish. *Recept.* naked, dotted.

Ess. Ch. *Receptacle* naked. *Down* simple. *Calyx* hemispherical, imbricated, with stalked membranous scales.

1. *P. rugata*. Wrinkle-scaled Podolepis. Labill. Nov. Holl. v. 2. 57. t. 208. Ait. n. 1.—Scales of the calyx rugged, obtuse.—Native of the south-west coast of New Holland. Sent to Kew by Mr. Peter Good, in 1803. It requires the shelter of a greenhouse in winter, and flowers in July and August. *Root* perennial. *Stem* herbaceous, either quite simple, or a little branched at the top only, about a foot high, minutely downy. *Leaves* linear, acute, entire; the lower ones somewhat lanceolate. *Flowers* few, on long, terminal, simple, scaly stalks. Their *disk* is about an inch wide; the *radius* short. *Calyx* of a tawny or rusty hue, shining, chaffy; the outermost scales spatulate.

2. *P. acuminata*. Sharp-scaled Podolepis. Ait. n. 2. (*Scalia jaceoides*; Curt. Mag. t. 956.)—Scales of the calyx even, sharp-pointed. Gathered in New South Wales by Mr. Brown, and sent to Kew by Colonel Paterfon, in 1803. It is a hardy greenhouse plant, flowering all through the summer, and differs from the former chiefly in having a larger flower, the *radius* being considerably longer, as well as in the sharpness of the *calyx-scales*. All the *florets* are of a golden yellow.

PODOLIA, in *Geography*, a province of Poland, bounded on the N. by Volhynia, on the E. by the palatinate of Kiev, on the S. by Moldavia, and on the W. by the palatinate of Lemberg, near the kingdom of Galicia. The country is fertile, but exposed to the plunder of barbarous nations, by which it has been cruelly ravaged. It abounds with a fine breed of horses and horned cattle. The inhabitants are warlike, and were formerly governed by their own dukes or sovereigns. In the fifteenth century it was the object of violent contests between the Lithuanians and Poles; but by the decree of a diet held at Lublin in 1569, it was annexed to Poland. Podolia consists of two palatinates, that of Podolia and that of Braclaw; both of which are annexed to Russia, except a small part towards the W., including Tarnopol, and a few more towns.

PODOLICZ, a town of Hungary, on the river Poprat; 12 miles S.W. of Palotza.

PODOLOBIUM, in *Botany*, from *πῶς*, a foot, and *λοβος*, a pod or legume, because that part is elevated on a footstalk. Brown in Ait. Hort. Kew. v. 3. 9. Sims in Curt. Mag. v. 36. 1477.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionacea*, Linn. *Leguminosæ*, Juss.

This genus is comprehended under *Chorozema*, by the writer of the present article, in Tr. of the Linn. Soc. v. 9. 251, nor does he perceive a character, by which they can well be separated, though Dr. Sims and Mr. Brown have thought otherwise. The keel in *Podolobium* is rather longer than the wings; in *Chorozema* shorter. The leaves are indeed opposite in *P. trilobatum*, Curt. Mag. t. 1477, but this does not appear to be the case with every species, nor is it very precisely or constantly so, even with the plant in question.

PODOLSK, in *Geography*, a town of Russia, in the government of Moscow; 28 miles S. of Moscow. N. lat. 53° 16'. E. long. 37° 29'.

PODOLYB, a town of Bohemia, in the circle of Koniggratz; 12 miles W.N.W. of Koniggratz.

PODOMETER, for PEDOMETER. See PEDOMETER.

PODONIPTÆ, formed from *πῶς*, ποδος, foot, and *νιπτω*, I wash, in *Ecclesiastical History*, a name given to some of the rigid Anabaptists, who enjoin it as an obligation upon the members of their community to wash one another's feet, in compliance with the example of Christ.

PODOPERURA, in *Ancient Geography*, a town of India, on this side of the Ganges, in the country of the people called Limyricæ. Ptolemy.

PODOPHYLLUM, in *Botany*, from *πῶς*, a foot, and *φυλλον*, a leaf. Tournefort originally called it *Anapodophyllum*, from *anas*, the Latin name for a duck; thus composing a hybrid word, unworthy of his taste and scholarship. De Theis erroneously lays the blame on Catesby. The idea of this appellation arose from a vague resemblance in the leaves, to the webbed feet of many aquatic birds, which is sufficiently intelligible in the word as Linnæus has pruned it.—Linn. Gen. 262. Schreb. 349. Willd. Sp. Pl. v. 2. 1141. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 287. Pursh. v. 2. 366. Juss. 235. Lamarck Illustr. t. 449. (*Anapodophyllum*; Tourn. t. 122.)—Class and order, *Polyandria Monogynia*. Nat. Ord. *Rhœadææ*, Linn. *Ranunculacææ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of three large, coloured, ovate, concave, ascending leaves, soon falling. *Cor.* Petals nine, orbicular, concave, plaited at the margin. *Stam.* Filaments numerous, very short; anthers oblong, large, erect. *Pist.* Germen superior, roundish; style none; stigma obtuse, furrowed. *Peric.* Berry globose, crowned with the permanent stigma, of one cell. *Seeds* numerous, roundish. *Receptacle* central, unconnected.

Eff. Ch. Corolla of nine petals. Calyx of three leaves, deciduous. Berry of one cell, crowned with the stigma.

1. *P. peltatum*. Duck's-foot, or May-apple. Linn. Sp. Pl. 723. Willd. n. 1. Ait. n. 1. Trew Ehret. t. 29. (*Anapodophyllum canadense*; Catesb. Car. v. 1. t. 24. *Aconitifolia humilis*, flore albo unico campanulato, fructu cynosbati; Mentz. Pugill. t. 11.)—Native of North America, from New England to Carolina, in shady woods, generally where the ground is moist, growing in large patches, and flowering in March and April. The fruit is the size of a common plum, green, eatable, known by the name of May-apple: the root is sometimes used as *Ipecacuanha*. *Pursh.* This is a hardy perennial herbaceous plant, known time out of mind in our more curious gardens. The root creeps, and resembles that of the *Helleborus niger*. *Stems* solitary, simple, round, smooth, about a foot high, crowned with two large, stalked, peltate, lobed, and jagged, smooth leaves, between whose footstalks grows a solitary, stalked, drooping white flower, an inch and a half broad, whose petals are curiously reticulated with veins.

The other species of Linnæus, *P. diphyllum*, Sp. Pl. 723, is separated from this genus by Barton, Michaux, and Pursh, and is thus distinguished.

Calyx of five leaves, deciduous. Petals eight, incurved. Capsule obovate, somewhat stalked, of one cell, bursting below the summit. Seeds several, oblong, tunicated at the base.—This has received the name of *Jeffersonia diphylla*. It belongs to *Oëandria Monogynia*, and appears to us a tolerably distinct genus, though retained in *Podophyllum* by Willdenow, and consequently in Hort. Kew. See Pursh v. 1. 268.

PODOR, in *Geography*, a fortress of Africa, on the Senegal, built by the French, and ceded to the English in 1763; afterwards retaken by the French, and kept by them in the peace of 1783. N. lat. 17° 1'. W. long. 14° 20'.

PODOSTEMUM, in *Botany*, derived from *πῶς*, a foot, and *στημων*, a stamen; so named by Michaux on account of the stamens being situated on a base or foot, which is divided into two branches.—Michaux Boreal-Amer. v. 2. 164. Willd. Sp. Pl. v. 4. 196. Pursh. v. 1. 3.—Class and order, *Monœcia Diandria*. Nat. Ord.

Gen. Ch. Male, *Cal.* Perianth none. *Cor.* none. *Stam.* Filaments two, capillary, connected at the base by a common footstalk; anthers somewhat heart-shaped, two-celled.

Female, *Cal.* Perianth none. *Cor.* none. *Pist.* Germen sessile, ovate, with two scales at the base, between which springs the foot of the stamens; style none; stigmas two, sessile, somewhat thread-shaped, a little shorter than the germen, spreading. *Peric.* Capsule ovate, eight-freaked, with two cells and two valves; partition parallel to the valves, slightly opening, not fixed. *Seeds* numerous, almost covering each side of the tumid partition, somewhat imbricated downwards, nearly oval.

Eff. Ch. Male, Calyx none. Corolla none. Stamens two, on a common stalk.—Female, Calyx none. Corolla none. Germen ovate. Stigmas two, sessile. Capsule of two cells and two valves, many-seeded.

1. *P. Ceratophyllum.* Michaux t. 44. Willd. n. 1.—Native of rocks about the falls of the river Ohio.—*Stem* a finger's length, thread-shaped, floating. *Leaves* pinnate, alternate; leaflets alternate, bristle-shaped, much cloven. *Flowers* axillary, solitary, the males inserted at the base of the females.

We are unable to trace any affinity to this curious genus. It has certainly no relation to *Ruppia* as Michaux has suggested. Mr. Pursh places it in *Monandria Digynia*.

PODRELSKOI, in *Geography*, a town of Russia, in the government of Viatka; 32 miles N.N.E. of Viatka.

PODRUS, a river of Walachia, which runs into the Syl, about three miles E. of Motril.

PODSPUSKNOI, a fort of Russia, in the government of Kolivan; 220 miles S.W. of Kolivan. N. lat. 51° 20'. E. long. 78° 34'.

PODSTEPNOI, a fort of Russia, in the government of Kolivan; 196 miles S.W. of Kolivan. N. lat. 52° 10'. E. long. 77° 40'.

PODULLUNG, a town of European Turkey, in Moldavia; 28 miles S.W. of Jassi.

PODURA, the *Spring-tail*, in *Entomology*, a genus of insects of the order Apterata. The generic character is, lip bifid; feelers four, subclavate; two eyes, composed of eight facets; the antennæ are filiform; the body is scaly; tail forked, bent under the body and acting as a spring; it has six legs that are formed for running. There are about thirty species enumerated by Gmelin. They are all small insects, which, in general, are found in damp places, under stones, on the bark of trees, &c. When disturbed they suddenly spring to a small distance by the help of a long fork, which is doubled under the abdomen, and which is suddenly thrown out during the act of leaping. They feed on the leaves of various plants; the larva and pupa are six-footed, nimble, and resemble the perfect insect.

SIGNATA. Sub-globular, brown; abdomen with fulvous spots at the sides.

* VIRIDIS. Sub-globular, green, with a yellowish head. Found on the leaves of the Polygonum fagopyrum.

* POLYPODA. Sub-globular, black; antennæ as long as the body, and tipped with white. Found on various plants, in this and other countries of Europe.

* ATRA. Globular, shining brown or black; antennæ long, composed of many articulations. It is found on the bark of trees.

* PLUMBÆA. Round, brown, with a blue gloss. It is found in similar situations with the last.

* MINUTA. Ovate, yellow, with two ferruginous spots on the back. This and the four following are found on plants in many parts of Europe.

* NIVALIS. Oblong, yellow, with two ferruginous spots on the back. It is frequently found in the winter on the snow in the footsteps of men and other animals.

* VAGA. Oblong, black; abdomen and antennæ with a white band.

* ARBOREA. Oblong, black, with white legs and forks.

* VILLOSA. Oblong, villous, variegated with brown and black.

CINETA. Cylindrical, grey, with a black belt, which is white on the fore-part. This and the next are found chiefly in woods.

ANNULATA. Livid, with black wings.

LIGNORUM. Lead-colour, with pale head, thorax, legs, and fork. This is a European insect, very small, and found in old wood.

PUSILLA. Cylindrical, bronzed with a white fork. It inhabits woods.

* AQUATICA. Black, aquatic. This is one of the most common species of the genus, measuring scarcely the one-twelfth of an inch in length, and entirely of a black colour. It is a gregarious species, and is occasionally seen assembled in vast numbers, particularly near the brinks of ponds, covering the ground to the distance of several feet, and sometimes even the surface of the water itself. On the ground its numbers are so great, as to have the appearance of scattered grains of gunpowder; and if closely examined, will be found in an almost perpetual skipping motion.

* FIMETARIA. White, terrestrial. This perfectly resembles the last except in colour, and in that the specific difference consists. It is found early in the spring in fresh earth, and also in damp places.

AMBULANS. White, with a bifid extended tail. Found among moss in different parts of Europe.

MONURA. Whitish, with an undivided conic tail. It inhabits Austria, and found with the last, which it resembles, but is much less.

* RUFESCENS. Reddish-yellow, villous; eyes black; fork whitish. A native of Austria, and found among stones.

VIRIDIS. Sub-cylindrical, yellow-green, with black eyes. This is found in Norway.

MOTITANS. Long, red, with an extended tail; antennæ and legs hyaline. This and the eight that follow inhabit Denmark.

SYLVATICA. Cylindrical, grey-brown; tail pointed and unarmed.

FEMORALIS. Oblong, cinereous; tip of the antennæ and legs white; tail of a sulphur colour.

AQUATILIS. Cylindrical, yellowish, with black eyes, back, and sides of the abdomen.

CRYSTALLINA. Body entirely hyaline.

LONGICORNIS. Cylindrical, yellowish; antennæ as long as the body, and with legs cinereous.

PALUSTRIS. Yellowish, with black eyes and line down the back; the fork is white.

LANUGINOSA. Silvery-gilt covered above with blue wool; antennæ recurved.

CRASSICORNIS. Dull blue, cylindrical and growing thicker towards the tail.

HUMICOLA. Blue-brown; antennæ short, thick; body cylindrical, and growing thicker towards the tail. Inhabits Greenland, as does the next.

MARITIMA. Blueish-black, with a whitish abdomen; body nearly round, and growing thicker towards the tail.

PODURA is also a species of *Cercaria*, in the class of *Vermes Infusoria*.

PODURUEVA, in *Geography*, a town of Russia, in the government of Irkutsk, on the Lena; 12 miles N.N.W. of Vercholenk.

POE, a river of the county of Tyrone, Ireland, which rises in the south-western part, and joins the Camern a little below Omagh.—Also, a town of Africa, in Biol; five miles S. of Portudel.

PŒANOPSIA, $\tau\omicron\omicron\omicron\omicron\omicron$, in *Antiquity*, a name sometimes given to the festival Pyanepfia.

PŒCILASIUM, in *Ancient Geography*, a town situated on the southern coast of the isle of Crete. Ptolemy.

PŒDICULI, or PŒDICLI, the name of one of the three people who composed the nation of the Lburni. They came originally from Illyria, about the 16th century B.C.; settling at first between the Alps and the Athesis, when they retired towards the south of Italy into Japygia. The Pœdiculi, Apuli, and Calabri spoke the same language, which they retained. Strabo.

POEJANNY, in *Geography*, a town of Bengal; seven miles S. of Koonda.

POEL, an island in the Baltic, near the coast of Pomerania, irregular in its figure, and about six or seven miles in circumference, containing several villages; two miles N. of Wisnar. N. lat. $53^{\circ} 57'$. E. long. $11^{\circ} 26'$.

POELEMURG, CORNELIUS, in *Biography*. was born at Utrecht in 1586, where he became the disciple of Abraham Bloemart; but he quitted that master as soon as he had made a reasonable proficiency in the art, and travelled to Rome. His first determination was to imitate the manner of Elstheimer; but he found himself so affected while he contemplated the works of Raphael, that he resolved on endeavouring to emulate the grace of that incomparable master; particularly in the naked.

He formed for himself a style that was entirely new, and in many respects preferable to the Flemish gusto; but it did not resemble the style of any Italian master, except in the ruins of the antique buildings, with which he adorned his landscapes; and which he had with great care copied after nature. He surpassed all his contemporaries in the delicacy of his touch, in the sweetness of his colouring, and in the choice of agreeable objects and situations. His skies are clear, light, and transparent; his back-grounds, ornamented often with the vestiges of magnificent Roman edifices, which always contribute to the harmony of the whole composition; and his female figures, which he generally represented naked, are beautiful and elegant forms. His greatest excellence appeared in the small pictures of his hand, for in the larger size he is not so deserving of commendation.

The Italians were excessively pleased with the works of Poelemurg; and some of the cardinals at Rome, of the finest taste, attended him frequently while he was painting, to observe his manner of working, and expressed their admiration in the strongest terms.

It was not without regret that he left Rome to return to his own country; though he afterwards found sufficient cause to be pleased with the honours he received from the grand duke of Florence, and the respect shewn to him in every city through which he travelled, as well as in his native city Utrecht. For, not long after his arrival, Rubens paid him a friendly visit, and having expressed a singular pleasure in examining the works of Poelemurg, he purchased several for his own cabinet, and bespoke others; by which generous conduct, so similar to that of Apelles towards Protogenes of Rhodes, he instructed the lovers of the art to estimate the merit of Poelemurg as highly as they ought; and at the same time advanced the fortune and the reputation of that artist.

By king Charles I. he was invited to the court of London; where he painted many curious pictures, for which he was nobly recompensed; and that monarch endeavoured

earnestly to induce him to continue in England; but his fondness for his own country prevailed over all other considerations, and he returned to Utrecht, where he acquired an affluent fortune, and lived in universal esteem. Several very eminent artists procured him to paint the figures in their works, particularly Steenwyck and Kierings; and the excellent perspectives of the former are sometimes rendered still more estimable by the pencil of Poelemurg.

The genuine work of this master are exceeding scarce; but his disciple, John Vander Lis, imitated his manner so successfully, that the paintings of Lis are very often taken for the works of his master. Fufeli's Pilkington.

POELSBROICK, in *Geography*, a town of Holland; seven miles S.E. of Gouda.

POEM, POENA, $\tau\omicron\mu\eta\mu\alpha$, a composition in verse, of a due length and measure.

POEMS, *Carmina*, are of various kinds; some denominated from the persons who first invented, or most used them; as the *Archilolian*, *Sapphic*, &c. Others from their composition, as the *monocolon*, consisting of one kind of verse; *dicobn*, of two; and *tricolon*, of three kinds. Others from their entireness or deficiency; as *brachycatalectic*, which in every verse wants two syllables; *catalectic*, which wants one; *acatalectic*, none; and *hypercatalectic*, which hath a syllable too much, which, if cut off at the beginning of the next verse, the verse is said to be *hypermeter*. (See ACATALECTIC, &c.) Others are denominated from the subject matter; as the *apobaterion*, *epibaterion*, *epinicion*, *epithlamium*, *genethliac*, *propemptic*, *elegiac*, *satiric*, *epicedion*, *epitaph*, *threnos* or *lamentation*, *encomiastic*, *panegyric*, *soteric*, *lyric*, *pastoral*, &c. Others from the manner of narration; as *exegetic*, which relates a thing under the author's own person, *dramatic*, and *epic*. See each on its proper head, EPIC, DRAMA, &c. To these may be added, odes, eclogues, and idylliums.

To this head must also be referred several other poetical compositions of a less serious kind, which the idly-labouring vein of little poets has produced into the world, and which, though frequently admired by persons of a low taste, are justly ranked by Mr. Addison in the class of false wit. Such are the acrostic, enigma, anagram, centochronogram, proteus, echo, &c.

PENITENTES, in the church of Rome, a designation given to heretics, who being admonished by the ecclesiastical judge, have abjured their errors, and given sufficient satisfaction to the bishop or inquisition. Confiscation of goods is a punishment common to all heretics; but if they confess and abjure of their own accord, without being formally prosecuted, this part of their punishment is usually remitted. See INQUISITION.

POEROU, in *Natural History*, a name given at Otaheite in the South-seas to the hibiscus tiliaceus of Linnæus, of the bark of which they make matting, coarse cloth, and ropes and lines from the thickness of an inch to the size of a small packthread. Hawkesworth's Voyages, vol. ii. p. 217.

PŒSTUM, in *Ancient Geography*, called also *Pofidonia*, a city of Italy, on a gulf of the same name, at some distance to the S. of the mouth of Silarus. Obscurity hangs over, not only the origin, but the general history of this city, though it has left such magnificent monuments of its existence. According to the learned Mazzochi, Pœstum was founded by a colony of Dorians, from Dora, a city of Phœnicia. It was first called Pœstan, or Postan, which in the Phœnician language signifies Neptune, to whom it was dedicated. It was afterwards invaded, and its primitive inhabitants expelled by the Sybarites, which event is supposed

Posed to have taken place about 500 years B.C. Under its new masters Pæstum assumed the Greek appellation "Posidonia," of the same import as its Phœnician name, became a place of great opulence and magnitude, and is supposed to have extended from the present ruins southward to the hill, on which stands the little town still called, from its ancient destination, "Acropoli." The Lucanians afterwards expelled the Sybarites, and checked the prosperity of Posidonia, which was in its turn deserted, and left to moulder away imperceptibly. Vestiges of it are still visible all over the plain of Spinazzo or Saracino: the original city then recovered its first name, and not long after was taken, and at length colonized by the Romans, U.C. 480. From this period Pæstum is mentioned almost solely by the poets, who, from Virgil to Claudian, seem all to expatiate with delight amidst its gardens, and grace their composition with the bloom, the sweetness, and the fertility of its roses. But unfortunately the flowery retreats, "Victuria rosaria Pæsti," seem to have had few charms in the eyes of the Saracens, and, if possible, still fewer in those of the Normans, who, each in their turn, plundered Pæstum, and at length compelled its few remaining inhabitants to abandon their ancient seat, and take shelter in the mountains. To them "Capaccio Vecchio" and "Novo" are supposed to owe their origin: both these towns are situated on the hills: the latter is the residence of the bishop and chapter of Pæstum.

The edifices which still subsist owe their origin, as it is most reasonably supposed, to the Dorians; and their form seems to indicate that they are the oldest specimens of Grecian architecture now in existence. In fact, the temples of Pæstum, Agrigentum, and Athens, appear to be instances of the commencement, the improvement, and the perfection of the Doric order. The first temple that presents itself to the traveller from Naples is the smallest: it consists of six pillars at each end, and thirteen at each side, counting the angular pillars in both directions. The architrave is entire, as are also considerable remains of the pediments at the W. and E. ends. The "cella" occupied more than one-third of the length, and had a portico of two rows of columns, the shafts and capitals of which, now overgrown with grass and weeds, encumber the pavement, and almost fill the whole area of the temple. The second temple has six columns at each end, and fourteen on each side, including those of the angles: the whole entablature and pediments are entire. The "cella," the interior of which is adorned by a double row of columns, supporting each another row of small pillars, had two entrances, one at each end, with a portico formed of two pillars and two antæ. The whole of the foundation and part of the wall of this "cella" still remain: under it was a vault. The third edifice is the largest: it has nine pillars at the ends, and eighteen on the sides, including, as before, the angular columns. A row of pillars, extending from the middle pillar at one end to the middle pillar at the other, divides it into two equal parts, and is considered as a proof that it was not a temple. Some suppose it to have been a curia, others a basilica, and others a mere market or exchange. In common to all these edifices it may be observed, that they are raised upon substructions, visible in all the Doric temples of Italy and Sicily, forming three gradations, intended solely to give due elevation and relief to the superstructure; that the columns in all rise without bases from the uppermost of these degrees; that these columns are all fluted between four and five diameters in height, and taper as they ascend, about one-fourth; that the capitals are all very flat and prominent; that the inter-

columniation is a little more than one diameter; that the orders and ornaments are in all the same, and the pediment in all very low: in fine, that they are all built of a porous stone, of a light or rather yellow grey, and in many places perforated and worn away. In the open place between the first and second temple were two other large edifices, built of the same sort of stone, and nearly of the same size. All the temples stand in a line, and border a street that ran from gate to gate, and divided the town into two, nearly equal parts. A hollow space scooped out in a semicircular form seems to be the traces of a theatre, which lying in front of the temples gives reason for supposing that other public buildings might have ornamented the same side and made to correspond in grandeur with that opposite; in which case few cities could have surpassed Pæstum in splendid appearance.

The walls of the town remain in all the circumferences, five at least, and in some places twelve feet high; they are formed of solid blocks of stone, with towers at intervals: the archway of one gate only stands entire. This rampart encloses a space of nearly four miles in circuit; and its extent, with the many towers that rose at intervals, and its elevation of more than forty feet, shew it to have been a work of great strength and magnificence.

Within these walls that once encircled a populous and splendid city, now rise one cottage, two farm-houses, a villa, and a church. The remaining space is covered with thick matted grass, overgrown with brambles spreading over the ruins, or buried under yellow undulating corn. A few rose bushes, the remnants of the "biferi rosaria Pæsti," flourish neglected here and there, and still blossom twice a year in May and December, as if to support their ancient fame, and justify the descriptions of the poets. Virgil and Ovid just mention the Pæstian roses: Propertius introduces them as an instance of mortality: Claudian employs them to grace a complimentary comparison: Ausonius alone presents them in all their beauty and sweetness.

"Vidi Pæstano gauderi rosaria cultu
Exoriens novo rosida Lucifero."

Idyll. xxv.

Amid these objects and scenes, rural and ordinary, rise the three temples, like the mausoleums of the ruined city, dark, silent, and majestic.

Pæstum stands on a fertile plain, bounded on the W. by the Tyrrhene sea; about a mile distant on the S. by five hills, in the midst of which Acropoli sits embosomed; on the N. by the bay of Salerno and its rugged border; while to the E. the country swells into two mountains, which still retain their ancient names "Callimara" and "Cantena," and behind them towers "Mount Alburnus" with its pointed summits. A stream called the "Solofone" flows under the walls, and by spreading its waters over its low borders, and thus producing pools that corrupt in hot weather, continues, as in ancient times (see Strabo, lib. v.) to infect the air, and render Pæstum a dangerous residence in summer.

Mr. Watkins has given accurate and minute delineations and measurements of these celebrated temples; and he, as well as other travellers, supposes, that the pillars of Pæstum were covered with a sort of plaster, or stucco, which, by its long duration, seems to have acquired the hardness and consistency, as it certainly has the appearance, of stone. Near Pæstum there are four mineral springs, to which is ascribed considerable efficacy in different complaints: from these springs flow a many streamlets, that form the "fiume salso" which falls into the Solofone close to the walls

of the city. Beyond the ruins, and separated from them by a little stream, now called "Pallena," rises the hill of the Acropoli, which merits the examination of the naturalist. As the plains that extend for some way on each side of the Silarus are very thinly inhabited, and at the same time covered with woods and thickets, they are become the resort of banditti and outlaws. At the mouth of the Silarus is the site of the temple of Juno Argiva, of high antiquity, and attributed even to Jason. Eustace's Classical Tour through Italy, vol. ii.

POESY, POESIS. See POETRY.

The word is formed from the Greek ποιησις, of ποιηω, facio, fabricor, fingo, I make, I frame, I invent.

Hence alchemy, or the art of making gold, we anciently called *poesy, chrysolopoesy, &c.*

POET, POETA, an author who composes poems or discourses in verse.

Cicero relates it as a saying of Democritus and Plato, that there could be no good poet *sine afflatu furoris, without a tincture of madness*; and Aristotle calls poets expressly, *maniaci, maniacs, madmen.*

M. Spanheim tells us that the Arab authors are more poetically given than those of any other people; and adds that there are more verses among the Arabians than among all the other nations of the world put together.

The Greek word ποιητης, poet, signifies maker, from ποιω, facio, I make; whence the poets were anciently also called *factifs*. The name they were properly denoted by among the Romans, was *vates*, which signifies also *prophet*.

By a law of the emperor Philip, inserted in the Code, lib. x. tom. lii. poets are expressly excluded from the immunities granted the professors of all other sciences.

Homer, Virgil, Milton, and Tasso, are the chief, almost the only, epic poets. Sophocles, Euripides, Shakspeare, Otway, Corneille, and Racine, are the best tragic poets. Aristophanes, Menander, Plautus, Terence, Fletcher, Johnson, Moliere, &c. the chief comic poets. Horace, Cowley, Malherbe, and Rousseau, excelled as lyric poets. And Juvenal, Persius, Regnier, Boileau, Dryden, and Oldham, as satiric poets.

POET Laureat. See LAUREAT.

This title, says Mr. Gibbon, is perpetuated by custom, rather than vanity, in the English court; and he adds, "from Augustus to Louis, the muse has too often been false and venal; but I much doubt whether any age or court can produce a similar establishment of a stipendiary poet, who, in every reign, and at all events, is bound to furnish, twice a year, a measure of praise and verse, such as may be sung in the chapel, and, I believe, in the presence of the sovereign. I speak the more freely, as the best time for abolishing this ridiculous custom, is while the prince is a man of virtue, and the poet a man of genius." Decl. and Fall of the Rom. Emp. vol. xii. 8vo. 1790.

POET, Provençal. See PROVENÇAL, and TROUBADOURS.

POET'S *Casta*, or *Poet's Rosemary*, in *Botany*. See OSYRIS.

POETICAL, ποιητικος, something that relates to poetry or poets. In this sense we say, a poetical genius, a poetical phrase, poetical licence, poetical fury, &c.

POETICAL *Epistle*. See EPISTLE, *Poetical*.

POETICAL *Justice*, is chiefly used in respect to the drama, to denote a distribution of rewards and punishments to the several persons, at the catastrophe or close of the piece, answerable to the several characters in which they have appeared. See CHARACTER.

Whatever difficulties and distresses the virtuous and innocent may labour under, and how prosperously soever it

may go with the wicked, in the course of the piece; the poet usually takes care to give each of them their due before he parts with them. But it is controverted whether this piece of justice be indispensable, and whether it may not be allowed to leave virtue oppressed, and vice flourishing.

POETICAL *Language*, is that language or style, which acquires a peculiar elevation and ardour from the sentiments of a mind, supposed to be animated by some interesting object that fires the imagination and engages the passions of the poet; and this language is very different from that mode of expression which is natural to the mind in its calm ordinary state. This language of passion or imagination is formed, *most commonly*, into regular numbers; because, though versification be, in general, the exterior distinction of poetry, yet there are some forms of verse so loose and familiar, as to be hardly distinguishable from prose, such as the verse of Terence's comedies; and there is also a species of prose, so measured in its cadence, and so much raised in its tone, as to approach very near to poetical numbers, such as the Telemachus of Fenelon, and the English translation of Ossian. The origin and first use of poetical language, says Dr. Lowth, are undoubtedly to be traced into the vehement affections of the mind. For what is meant by that singular frenzy of poets, which the Greeks, ascribing to divine inspiration, distinguished by the appellation of *enthusiasm*, but a style and expression directly prompted by nature itself, and exhibiting the true and express image of a mind violently agitated? Hence proceed sudden exclamations, frequent interrogations, apostrophes, even to inanimate objects; for, to those who are violently agitated themselves, the universal nature of things seems under a necessity of being affected with similar emotions. Every impulse of the mind has not only a peculiar style and expression, but a certain tone of voice, and a certain gesture of the body adapted to it. Some, indeed, not satisfied with that expression which language affords, have added to it dancing and song; and as we know there existed in the first ages a very strict connection between these arts and that of poetry, we may possibly be indebted to them for the accurately admeasured verses and feet, to the end that the modulation of the language might accord with the music of the voice, and the motion of the body.

Most languages have their poetical words, which are seldom, if ever, used on other occasions. These words are of great use to the poets, who are thus enabled to raise their style and diction to the poetical character with the greater ease. The French lament the want of such appropriate words in their language; from a defect of which the style of their poetry is not sufficiently distinguished from the common language. It is too reserved, not being allowed any boldness or flights, but such as might pass in prose. To this circumstance is attributed, in a considerable degree, the little success which their authors have met with in epic compositions. Phrases also, as well as words, which might originally have been in common use, are now restricted to poetical compositions. The language of Homer differs materially in the mode of inflexion, the syntax, and even the words, from that which was written and spoken in Greece in the days of Socrates; after an interval of 400 years. Homer, however, must have written in a dialect that was intelligible, though not perhaps in familiar use at the period in which he wrote. Notwithstanding the change that must have taken place, during so long an interval, in the style both of discourse and writing, the Iliad continued to be the standard of heroic poetry, and was considered as affording a specimen of the most perfect poetical language; though Aristotle

Aristotle had doubts about the correct meaning of particular expressions. If Chaucer had ranked so highly as a poet as Homer did, and the English language under Edward III. had been as perfect as the Greek was in the second century after the Trojan war, his style would probably have been the model of poetical language at this day; as Petrarch, his contemporary, sets even now the standard for the best Italian poets. Many words and phrases, used by Ennius, a Latin poet, but not adopted by any prose writer now extant, are to be found in Lucretius and Virgil, and by them transmitted to succeeding poets. These form part of the Roman poetical dialect, which, as the writings of Virgil, where it is found in perfection, testify, was very copious. The style of this charming poet is so different from prose, and so peculiar, that it cannot be analysed on the common principles of Latin grammar; and yet no author can be more perspicuous or more expressive; or knew better, according to the judgment of Quintilian, to improve even Grecism, and old words by which he seems to be attached, into decoration.

The poetical dialect of modern Italy is so different from the profane, that Petrarch or Tasso can scarcely be construed by those who are well acquainted with the common language of that country; and yet it is not probable that Petrarch, whose works furnish a standard of the Italian poetical diction, made any material innovations in his native tongue. The French poetry, in general, is distinguished from prose rather by the rhyme and the measure, than by any old or uncommon phraseology. Nevertheless, the French, on certain subjects, imitate the style of their old poets, particularly of Marot, and may therefore be said to have a poetical dialect, though less extensive than that of the Italian, or even of the English. The English poetical dialect is not characterized by any peculiarities of inflection, nor by any great latitude in the use of foreign idioms. Words and phrases, however, occur in English poetry that are not to be found in prose writings. Several of them will occur to the readers of our poets. The introduction of such words and phrases serves to render the poetical

style more melodious; and when they are known to be ancient, more solemn, and by association more elegant and sublime. The following lines afford a specimen of poetical words, which no one can read without perceiving their effect:

“The breezy call of incense-breathing morn,
The swallow twittering from the straw-built shed,
The cock’s shrill clarion, and the echoing horn,
No more shall rouse them from their lowly bed.”

We may add, that tropes and figures serve very much to improve poetical language. They render it more pleasing, and greatly contribute to its effect. They supply the unavoidable defects of common language; they are also favourable to delicacy of expression; they promote brevity, which, without interfering with perspicuity, is very pleasing; they give strength and energy to language, and make a deep and durable impression on the mind; they are the appropriate language of emotion and passion. See **FIGURE** and **TROPE**, and each figure under its proper name, as *Apostrophe*, *Hyperbole*, and *Prosopopeia*; which see. The sound of words ought also to be regarded in poetical language; as it contributes to harmony of composition, without which no poet can be popular. See **VERSE** and **RHYME**.

POETICAL Licence. See **LICENCE**.

POETICAL Numbers. See **NUMBERS**.

POETICAL Rising and Setting. See **RISING** and **SETTING**. The ancient poets, referring the rising, &c. of the stars to that of the sun, make three kinds of rising and setting, *viz.* cosmical, acronical, and helical.

POETICAL Theology. See **THEOLOGY**.

POETICS, POETICE, ποιητικη, the doctrine of poetry, or the laws and rules of conducting pieces, or compositions of poetry. Aristotle’s *Poetics* is a work very highly valued; and M. Dacier’s comment upon it is one of his best pieces. Horace, Vieta, Vossius, and Scaliger, have likewise published *Poetics* in Latin; the duke of Buckingham in English; and Menardiere, Hedelin, and Despreaux, in French.
